The architect who decides to use photography as an aid in his study and practice should understand certain of the technicalities. The questions which present themselves are :—What is the best camera for architectural work? What lenses should be used? What photographic plates and papers should be employed?

Before anything can be done, the size of the camera must be decided upon. The ordinary sizes are: 4¼in. by 3¼in. (quarter-plate); 6½in. by 4¾in. (half-plate); 8½ in. by 6½ in., (whole plate); 10 in. by 8in.; and 12 in. by 10 in.

It is generally agreed that the larger sizes are the best for architectural work. But the larger the size the more expensive it will be. Besides this, the weight of the camera is a serious matter, especially as in the majority of cases the work would be done at a distance from home. For these reasons it may be conceded that the half-plate is the most serviceable. When lantern-slide work is contemplated, the quarter-plate is generally selected, as that is the most suitable size for the purpose.

If a good lens is employed, the quarter-plate size might be used for all work, as the photographs can be enlarged satisfactorily.

A camera for architectural work should have considerable rise and fall at the front, a good swing-back, long extension for long-focus and telephoto lenses, parallel or only slightly conical bellows (which prevent the cutting-off of the edges of the photograph when a short-focus lens is used), and at least three or, better, six double dark slides.

As to lenses, it is best to have a set of different foci and of a good make. They should be of rectilinear type.

For average work the rapid rectilinear of about 7in. focus is most serviceable on a half-plate. Long-focus lenses are useful in detail work, and wide-angle lenses are essential in confined positions.

The telephoto lens is a most valuable acquisition in the equipment. Some of the best examples of detail work are at too great a distance from the position available to give a photograph of a satisfactory size, but a telephoto lens enables one to obtain it to a larger scale with the same extension of camera. As this lens is not of a fixed focal length, the scale of the photograph can be altered at will, which is often useful.

Ordinary plates of a good make are the best for architectural work, especially for interiors, although in dark interiors where very long exposures are requisite rapid plates may be used with advantage. Isochromatic plates are useful when the lighting of the interior is yellow. In interiors where the light from windows, etc., would be likely to cause halation it is necessary to use backed plates.

The development of the negative requires care on the part of the operator, but this question cannot be discussed now. It may be mentioned, however, that the architect-photographer should do his own development.

The chief printing processes are silver printing-out, platinotype, carbon and bromide ; the decision as to which should be used depends upon circumstances.

A silver printing-out process, such as the well-known P.O.P. of various makes, produces excellent results, but if permanent photographs are required, platinotype or carbon processes should be used. For enlargements, bromide papers are most satisfactory.

DISCUSSION.

Mr. Arnold Mitchell said a level should always be used on a camera. Mr. George Scamell advised the placing of a scale on the building, so that it might be reproduced in the photograph ; he recommended a paper scale published by the Society of Antiquaries, price 6d. He always used a whole-plate camera himself. A pendulum level should be fixed on the back to enable the vertical lines to be accurately obtained. A camera for architecural work should have its lens fixed at the top of the front, not in the centre, as in nine cases out of ten this would avoid the front being raised. An ordinary stigmatic lens of three foci saved carrying several lenses. He had largely used Wellington Ward's stipping films, which saved much in weight and had practically no halation. "Ortol" was as good a developer as "pyro" and it did not stain the fingers. Starch paste should only be used for mounting. He thought it better to over-expose rather than under-expose. Mr. Hugh Stannus described a mirror reflector he had made for photographing ceilings, etc. ; this consisted of a piece of mechanically-planed glass carefully silvered, and was placed at an angle of 45 degrees with the camera.

*Summary of paper presented before the Architectural Association in London.

ECCLESIASTICAL ART IN IRELAND.

It is plainly evident from the address he recently delivered at a meeting of the Maynooth College Union that the Rev. J. O'Donovan, of Loughrea, not only holds strong and sound views on ecclesiastical art, but he knows how to express himself strongly. The talk of a revivial of industries in Ireland led him to urge a revivial of Irish art in church decoration. He "went for" modern stained glass, sculpture, and painting as seen in the Church of Ireland. Stained glass, he remarked, is one of the most familiar forms of decoration in our churches. There is scarcely a church in Ireland that has not one or more stained glass windows. In some of the large churches the cost of those windows runs up £3,000 or £4,000. It may seem a rather sweeping statement to make, but it is a statement upheld by every expert authority on art, that generally—indeed, in almost all cases—this glass is, from an art standpoint, beneath contempt. It is as a rule gaudy in colour, badly drawn, vulgar in design, and where perspective is attempted, false in perspective. It is, moreover, bad glass. There are many varieties of glass known by the very indefinite name of stained glass. There is pot-metal, which alone was used in the best period of stained glass. In this glass the colour runs through and through the texture of the glass, the colour and the glass being fused together in the pot. Then there is enamelled glass, in which the colour is enamelled on the glass in soft pigment. When stained glass manufacturers advertise they always profess to supply a window, as the advertisement puts it, "best pot metal antique." When the window is put up it is not unfrequently very poor enamelled stuff.

There is, he went on, a craze for pictured windows, large and elaborate subjects that tell stories. This is a complete misunderstanding of the limitations of stained glass. In the thirteenth century, when the finest glass was produced, there were no elaborate pictures ; the effects were produced by careful leading and a most delicate choice of differently coloured glass. If figures were necessary they were outlined in leads, the feature and other details being worked in with the smallest possible use of brown pigment. The artist craftsmen of these times knew exactly what could be done in glass and what could not. They knew that the first quality of a window is to give light, and next if it is to be coloured its function is to give coloured light of the finest kind. For that reason the thirteenth-century artists always aimed at colour and translucency. Now the modern windows sin in almost every instance against this primary law. The function of the modern window seems to be to shut out light, or where it is let in to pass it through thick dirty brown or other paint with which the glass is thickly plastered. Take some good glass of the best period and compare it with the modern. The best examples are to be seen at Chartres Cathedral outside Paris. There are also a few fine examples which somehow escaped the vandalism of Puritanism in some of the English cathedrals—in York Minister, in the east window, in Salisbury, Lincoln, Westminster, and others. These windows, when the sunlight passes through them, are like mosaics of different coloured jewels, they never look gaudy because of the extreme purity of their tones. Sunlight through a modern window is robbed of all its beauty,

and strikes the eye as a dirty drab. Apart from quality and colour, the modern stained glass window is bad and vulgar in design. The human figures are certainly not of any race that inhabits this earth in any know period of history. But even given correct drawing, the effects of light and shade are always wrong; they are impossible with light always falling on the picture from behind.

Another important branch of church decoration, continued the reverend critic, is sculpture. To judge by the Irish churches it is a lost art. Here again the foreigner holds the field. Go into our churches and you will find that the more pretentious of the statues come from Italy and Munich. If you venture to say you don't like the work the good priest looks you all over with a smile of superior pity, and reduces you to your proper level by the clinching remark, "Why, this statue was made at Carrara." Of course there are marble quarries at Carrara and stone-cutters of very great technical skill, but art, with an idea behind it, especially on religious art—no! Take a statue of St. Joseph, admitting that it is modelled correctly, which it very often is not, does it convey any religious idea to the mind? Only for the label it might just as well have stood for Marcus Aurelius or any other character that you like to think of. Church painting is at just as low an ebb. All our church-painting, with such few exceptions as are hardly worth noticing, comes from abroad. Rome, Germany, Belgium, France, are the principal markets. We may dismiss this branch of church art in a few words. The paintings are either attempts at religious art not above the level of daubs, or fairly good pictures—not religion. For some time past the country has been flooded by good and bad copies, generally made in Germany, of paintings entitled Madonnas, Magdalens, &c. The originals were painted by men who had no religious belief and are frankly naturalistic in treatment. Yet those pictures, often the grossest portrayal of human passion, are hung up in convents and other religious buildings, even in churches, to inspire the reverence and devotion of the faithful. There are other branches of church decoration—brass, gold and silver work and woodwork generally made in Birmingham or in Belgium.

We have first an immense consumption of decorative work that shows no sign of decreasing. We have most of this produced aboard, and done almost as badly—considered artistically—as one could possibly conceive. This work, if it could be done in Ireland, would be an immense industrial gain, and would provide work for thousands of hands. But it has behind it far higher possibilities. It may make Ireland a great centre of art production. Ireland once was remarkable for its art products. "The barbarians by the Western Sea" knew the exquisite art of enamelling on various metal when it was unknown to the Greeks and Romans. The country that produced the Tara brooch and the cross of Cong and the Ardagh chalice had surely a highly-developed art sense. In architecture our fathers did work of wonderful beauty. The Romanesque ornament at Cong, at Dysart O'Dea, the whole design of that imperishable memorial to Irish genius on the Rock of Cashel—Cormac's chapel—indicate what Irish art might have come to had it not been arrested by foreign influence. The revival, if there is to be a revival, will rest with the Church, which has at all times been the centre of art production.

LOMBARDIC COLUMNS.

Among the characteristic peculiarities of the Lombardic style, the following may be enumerated as the most obvious and the most general: Columns with cylindrical shafts, and varying greatly in their proportions, some being of the average height of the Roman Orders, others extremely short, either in proportion to their diameter or their capitals, or else exceedingly tall, and when attached to walls elongated into a mere rod, or vertical convex moulding, surmounted by a capital. Instances of fancifully shaped or decorated shafts are by no means unfrequent, some being zigzaged horizontally, or polygonal in plan, or embossed with sculpture, or either twisted or cut into spiral grooves or mouldings. Equal diversity—not to call it extravagance—prevails in the capitals, which, as far as general mass and outline go, bear some analogy to the Corinthian. If, however, some capitals are much decorated, others are nearly plain, and these are frequently in the form of an inverted cone, but in such manner as to present four flat sides or faces which again are occasionally more or less ornamented. In bases there is much less variety, they being for the most part only a series of mouldings in rude imitation of the common attic base. But one very great singularity in this style connected with columns is that of placing them upon the backs of couchant animals or other figures, which serve as pedestals to them. Whimsical as it appears to us, it may very probably have originated, not altogether in caprice, but have been occasioned by employing materials and fragments taken from ruined edifices, where columns, being found too short for their intended situation, were raised or stilted up by being set on other fragments for which purpose remains of sculpture may have been adopted, either because they chanced to be at hand or because considered more ornamental and as adding richness to the column itself. Upon the same supposition we may easily account for the great variety of columns and capitals in the same building, namely, that they were ornaments collected at random from the remains of other structures, and that the irregularities thus occasioned in the first instance grew by degrees to be a matter of taste, and was adopted as a matter of choice. Columns of the kind just specified were, however, by no means very usual, and are chiefly to be met with in those forming porches or decorating the chief entrance to a church, as in that of St. Ciriaco at Ancona, and in San Zeno at Verona. Although not invariably so, columns are to be understood as accompaniments to arches which spring from them, and arches applied in different ways are very predominant features of the style. Besides giving the form to doorways and windows, they were employed for decorating the faces of walls in very nearly the same manner as in the kindred Norman style.—The Architect.

Mr. Hebert, the well-known French Canadian sculptor, has been commissioned to prepare a statue to the late Joseph Howe to be erected in Parliament House Square, Halifax, on the 100th anniversary of Howe's birth in December next.

The members of the O. A. A. and others who had the pleasure of meeting Professor Nobbs of McGill University, on the occasion of the recent O. A. A. Convention in Toronto, will regret to learn that, immediately following his return to Montreal, he was compelled to enter the hospital and undergo an operation. It is gratifying to learn, however, that he is now on the way to convalescence.

Of the half million dollars expended in sculptural decoration for the St. Louis Exposition, women have secured a considerable part. Six are included in the distinguished corollary of artists selected to embellish the buildings. In the Art Palace the work of feminine painters compares favorably with that of men. In rug weaving, working in metal, book binding and decorative work, woman has made great progress.

PLUMBING PRACTICE UP-TO-DATE.*

By Lewis Le Grow, Toronto.

The plumber has always stood for one who works in lead; the name stands for the same to-day, but it has advanced to a position where it not only represents one who works in lead but also one who is responsible for the health of the community more than any other, and as it has been stated that there is nothing new under the sun, plumbing as we find it to-day is a contradiction of that statement.

It is not long since that plumbing was looked upon as the least important part of a house. It was considered quite up-to-date to have a 4-inch tile drain, extending from sewer on street to the most convenient point and then to run branches to different houses without respect to what basements it went through, or how complicated it might be constructed. Once an obstruction occurred in the main drain all properties dependent on it suffered in consequence. To-day every house must have its own drain carried outside of foundation walls.

Light soil pipe was universally used to bath room, then extended with galvanized iron through roof with slip joints. Every fixture in the bath room would be connected into heel or closet bend and it often connected to soil pipe with a putty or rust joint. Then for the finishing of the job, Pan, Hopper or Demerest closet was considered quite a luxury, but on no condition was any part of it to be exposed that might allow the free circulation of pure air, which in the opinion of many was not so important as that everything boxed in and painted so that microbes and other parasites might be the better increase.

With the advance of practical and technical education, laws have been adopted to compel people to appreciate good plumbing. Our improvements have affected all fixtures and condition of work, the most important being our system of backventing and syphon jet closet.

We will briefly notice the most important article of plumbing construction, namely, traps. A great many have been placed on the market, but from experience I find that traps with internal partitions are most dangerous. A flaw may exist in this partition above the water line and allow gas to enter the house. When we consider that it is not the depth of seal that offers the most resistence to syphonage, but the amount of water and that it is the depth of seal and not the amount of water that offers the greatest resistance to sewer gas, it is very important that the trap should be well made and work on the centrifugal principle with a back vent to relieve the trap from the pressure of sewer gas. The main trap in the sewer in my opinion should not be tolerated; it prevents the ventilating of sewer through the main stack and it also acts as an impediment to the flow of sewerage.

House drains should carry waste out of the house—not much nor little, but all—and do it promptly; when that which is intended for the street sewer is started on its journey it should be afforded a means of reaching its destination at once and without interruption, not a particle of filth should be allowed to cling to the sides of waste pipes nor be held in solution in some trap until it begins to decompose and give off its dangerous gases.

Kitchens of hotels and restaurants should have a grease trap situated in an open place and easy to clean out; all back vents on bath traps should rise perpendicular through the floor and not be bent so low on the trap as would allow any particles of waste matter to accumulate around its opening and stop the free ingress of air. When this occurs there is danger of syphoning. Where vents from traps connect with wrought iron pipes square elbows should not be used, angle fittings are the only perfect connection. Water closets such as the Richelieu and improved Sanitary should not be used on sanitary work owing to the vent being made a part of the trap and crockery is not a safe thing to connect with lead; the vent being rigid, any settling of the floor or movement of the fixtures is likely to break off the vent horn. And to prevent any settlement of soil pipe, it should rest on a foundation of brick or stone properly built by a mason. There are too many stacks of soil pipe connected with the tile drain allowed to rest on a bed of sand supported only with iron hangers. We have all had experiences of a very unpleasant nature from hoar frost accumulating at top of 4-inch soil pipe above roof, stopping the ventilation of fixtures and causing syphonage, allowing sewer gas to saturate the room in a short time. All soil pipe passing through the roof should be increased to 5-inch from underside of same.

Another point of very great importance to the health of the people is the proper construction of a cess pool. It should be so placed that the liquid from it into the surrounding soil may not affect the water supply or leak into the cellar of the house.

(Continued on page 55.)

NOTES.

The specification of the new naval barracks at Chatham, Eng. stated that the floors were to be caulked, and the contractor, entered into a sub-contract for the work. The space between the boarding was said in the contract to be ⅛ inch. Owing to the shrinkage of the timber this space was increased, and the sub-contractors claimed to have expended 137l. on the additional glue and oakum that was required. The defendants admitted the shrinkage, but maintained that it occurred after the caulking. The jury gave a verdict in favor of plaintiffs, with 118l. damages.

When properly built of brick or stone with loose joints, with drain tiles to distribute the water, leaving behind the solid matter which should be removed when necessary, we will find the sanitary arrangeme 's equal to our city sewerage system.

The improvements of water closets have been remarkable, thanks to our manufacturers and the healthy competition amongst us to introduce to our customers the very best appliances. The syphon water closet takes first place to date. The energy of the flush is exerted without loss under atmospheric pressure; it produces complete syphonage. In the washout closet before the trap is reached much of the energy is wasted. Water closets constructed in basements should be arranged with a due regard to the effects of the sun, for there is no disinfectant so sure as sunlight and ventilation. Local vents should always be connected directly with the closet bowl to be of the most practical benefit, and where it connects with the chimney it should run into a piece of iron pipe as galvanized iron in time will become rusted.

A great source of trouble in our homes which we fail to be conscious of is the refrigerator. Into it is placed the important things of life and it is surprising how little attention is paid to the proper disposal of the waste water. It should be conducted into an open pan or sink, placed some distance from the end of the waste pipe, with a good air space. This fixture properly trapped and ventilated and supplied with faucet would remove a great source of unpleasantness.

House drainage at the present time consists of two parts, soil and waste pipe above ground and tile drains under ground.

For each part there are different tradesmen, the plumber taking care of work above ground, the drainmen that below ground. The connection of soil pipe with the system of drainage belongs to the plumber, and he is responsible for the same. This connection has to be made with cement, and the most important of all, for it is covered up and not likely to be seen again until trouble occurs in the drainage. If then it is admitted that iron pipe free from all defects is necessary above ground, is it not of more importance that the same soil pipe should continue uninterrupted to a point outside of the foundation walls.

In this city materials out of which house drains have been constructed have remained the same while other improvements were being made, and it is time that we should take the initiative and have our drainage system placed in a proper position and constructed of material that the first cost will be the only one, and that the interest of men engaged in the manufacture of pipe must take second place to the health of the people. The ordinary tile drains must be discarded since they cannot be secured against breaking and defective joints. Perfect joints and not mere increasers must be used between sections of drains and soil pipes inside of any building. The removal of main traps and the purification of sewer gas that is the most poisonous, namely, sulphurated hydrogen and sulphide of ammonium.

It is not extravagant to talk about a perfect system of drainage since lasting material can be used. There is no more reason why there should be perishable material used and defective joints made in house drains than in the pipes which convey the gas. The latter are air tight and gas tight; so should the former be. House drains should be recognized as a part of a house, not as something that will be covered up and not of so much importance. The supervision and the construction of house drainage should be put under the direction of the responsible and practical plumber, and not as at present, any man who can do it the cheapest.

It appears very simple to those who take no further thought of it that the essential element in plumbing is the ventilation of the sewers, but conditions and details of actions require to be studied, taking into consideration the disregard many people have for the plumbing fraternity, and it will be necessary for us to use scientific knowledge and practical experience to improve the sanitary comforts for all conditions. A united co-operation between the medical, architectural and engineering societies, lead on by our own professional plumbing and heating engineers, might bring the day when we will fully realize that an Omnipotent Providence has placed on us a responsibility of educating the indifferent to an understanding that the highest material things in life are cleanly surroundings and a pure system of ventilation.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingle stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

Another Combine.

The manufacturers of builders' hardware in the United States are reported to have come to an understanding whereby all the designs have been classified and priced. It is said that the better goods are to be advanced from 25 to 50 per cent. at once, and that a 10 per cent. advance on all goods is slated for the near future.

Students' Competition.

A considerable number of architects and architectural students visited and inspected the exhibition at our Montreal office of drawings submitted in our recent students' competition. Drawings submitted in future competitions will in like manner be exhibited in Montreal, in the hope that they may awaken interest and a spirit of emulation among students of architecture in that city.

The Law Affecting Architects and Contractors.

Architects and contractors, especially those who now or in the future may have to do with the erection of buildings in the Province of Quebec, may with profit read the series of lectures by Mr. J. S. Archibald delivered before the P.Q.A.A., publication of which is commenced in the present number. These lectures deal in a very clear and concise manner with the legal responsibilities of architects and contractors under the Civil Code of the Province of Quebec.

The Study of Building Sites.

We were much struck with the remark of a young architect while showing the plans which he was preparing for some new houses, that he had not visited the site and did not know its exact location on the street. We wondered how far these houses when built would prove satisfactory to the owner and future occupants. Architects young and old should bear in mind that a careful study of the site is the first requisite to the production of a successful building, and is therefore a duty which they owe to themselves as well as to their clients.

Cement Construction.

Several articles are in course of preparation for our May number treating of the physical properties of cement, methods of cement testing and using cement in construction. Particular reference will be made to methods of reinforcing concrete with steel. In view of the truly wonderful progress which is taking place in the use of cement for construction purposes and the certainty that the material will come into more general use in the future, a consideration of the subject at some length in these columns seems advisable and likely to be of interest and value to our readers.

Safety From Frost.

The experience of last winter should lead to the adoption by Toronto architects, engineers and contractors of a new formula to govern the depth to which foundations should be carried in order to escape frost. The practice until this year was to regard 3 feet 6 inches as the utmost limit of depth necessary to ensure safety. This theory has been dispelled by the extreme frost of last winter, which in some instances caused pipes to freeze at a depth of five feet below the street surface. In Montreal,

where the winters are usually much more severe than in Toronto, the rule is to place all water and other pipes at least seven feet below ground.

The Collapse of a New York Steel Building

On March 2nd the Darlington hotel building, an eleven storey steel frame structure in course of erection at 59 West 46th street, New York, suddenly collapsed and twenty-one persons were killed. There was an outer casing of brickwork covering the steel framework. The floors were supported by cast-iron columns seated on separate off-set brick piers with concrete footings and granite caps and placed 13 feet apart. These columns carried I-beam girders and floor beams about 12 and 8 inches depth, the average spacing of the floor beams being 4 feet. Beam, column and girder connections and splices were, according to the specifications, to be bolted, no rivets being used. There were no knee or other braces. The building was designed to carry a floor load of 130 lbs. per square foot. Beams and girders were proportioned for working loads of one-quarter of this load and columns for one-fifth. The architects who prepared the plans and specifications were not employed to superintend the construction, but this duty was largely entrusted to one of their draftsmen who left their employ for the purpose. The original plans were submitted to the Building Department and approved. Atterwards these plans were changed aud a new set of plans submitted which were rejected; then a third set was prepared which were also rejected. The contractors then proceeded with the erection of the building in violation of a notice from the Building Department that operations must cease until the building laws were complied with. Objection was made by the Department to the improper method of bolting beam, girder and column connections, and to the relative rate of construction of walls and steel work. The Building Department found itself powerless, however, to enforce the building regulations, and the contractors taking advantage of this fact, proceeded with the construction of the building.

When the collapse came a number of arrests were made and an investigation was instituted by a Coroner's Jury to ascertain the cause. The jury reported finding the owner and steel work contractors "grossly criminally negligent in the methods adopted and followed by them in the erection of the building". The jury further made the following recommmendation: We recommend that the practice of the erection of buildings without the superintendence of the original architect or a competent builder of at least five years' experience be prohibited by law. We further recommend that the Building Department of the City of New York have a corps of competent engineers to inspect the erection of all buildings requiring engineering skill, and that a copy of the approved plans of each building be kept on the premises during construction." The building regulations at present in use in New York were formulated only three or four years ago by a Commission appointed for the purpose, and were thought to be very carefully and skilfully prepared to cover all possible contingencies. The occurrence to which we have referred, however, shows them to be faulty in at least one most important particular, and should lead the authorities of New York and other cities to carefully revise and make as effective as possible their regulations governing the construction of important buildings.

THE TORONTO FIRE.

Two things have specially impressed us in connection with the disastrous fire in Toronto—one that the insurance companies required only two days to decide to advance insurance rates from 50 to 75 per cent.; the other, that the City Council of Toronto have had under consideration for two or three years the framing of an up-to-date building by-law, and no decision has yet been reached. This is a fair example of the relative speed with which private corporations work in com-

CORNER OF BAY AND WELLINGTON STREETS, NEAR WHICH THE FIRE ORIGINATED.

parison with public bodies. Perhaps the thing that most requires prompt action at the present time is the adoption and putting into force of proper building regulations. There is now an opportunity such as will probably never occur again of improving the character of buildings for business purposes. The opportunity should not be lost. It would be unreasonable to compel firms who have been burned out to defer the rebuilding of their warehouses, therefore the Mayor should insist upon immediate action being taken in the direction of

WAREHOUSES ON SOUTH SIDE OF WELLINGTON STREET, WEST OF BAY STREET.

the consideration and adoption of regulations which will insure that none but substantial buildings will be erected in the place of those destroyed.

This fire, as well as those in Baltimore, Rochester, and elsewhere has clearly demonstrated the fact that no better check can be put in the way of a conflagration such as Toronto has experienced than solid brick walls. Unfortunately, many of the warehouses which stood in the path of this fire were so flimsily constructed that the walls were not strong enough to stand alone, and when attacked by the fire toppled over leaving a clear path for the extension of the conflagration.

The insurance companies should change their methods of assessing buildings, and offer greater inducements than heretofore to the owners of substantially constructed buildings. In the past buildings have been simply grouped into classes, each class being rated the same regardless of differences in construction. This method should no longer prevail, but substantial inducement should be given those who will put up solidly built structures and employ fire-proofing methods. When it is considered what great losses have been incurred by the occupants of buildings destroyed in the recent fire because of interruption to their business, it will be seen that, apart altogether from the question of insurance rates, it would pay the owners and occupants of such buildings to use a higher standard of construction.

VIEW ON WELLINGTON STREET.

At least one important building was saved by the fact that the windows on one side were protected by iron shutters. The advantage of protecting windows by this or other methods equally effective is beyond question. The value of open spaces in preventing the progress of fire has also been demonstrated. Had it not been for the open spaces immediately to the west of the Custom House and east of the Queen's Hotel, and the fact that facing on these open spaces were walls of solid brick, the fire would doubtless have spread further in both directions. While the water pressure was very defective, yet in the face of the unfavorable weather conditions prevailing this fact had little bearing on the situation. No matter what the pressure might have been, the fire could not have been stopped by the fire brigade after it had once got headway. In this connection it seems pertinent to enquire if, by the exercise of better judgment on the part of the heads of the Fire Department, the fire might not have been confined to the building in which it originated. It is said to have stated at the rear of the building, and that, instead of attacking it there, the firemen broke open the front doors, thus allowing the flames to be driven by the fierce wind through the building and across the street, setting fire to the large warehouses opposite. It would seem to be the duty of the Chief of the fire Department to direct his men on the street instead of as on this occasion entering burning buildings, where he was partially disabled, thus throwing upon the shoulders of subordinates the direction of affairs.

"Here all is sunny, and when the truant gull
Skims the green level of the lawn, his wing
Dispetals roses; here the house is framed
Of kneaded brick and plumed mountain pine,
Such clay as artists fashion, and such wood
As the tree-climbing urchin breaks.
My house, I say."

—LOUIS STEVENSON.

LESSONS FROM THE SOUTH KENSINGTON MUSEUM.

One of the best things in London is the South Kensington Museum. It shows examples of nearly every kind of design and is invaluable to designers of all kinds. Books and photographs are very well—there are books and photographs in the Museum Library—but when it comes to really feeling at home with design, to know what it is really like and measure one's mind against it with certainty, there is nothing like an example. For purposes of study it need not be the original; a model is as good. A model may fail to convey exactly the sentiment attaching to its original, or the beauty it has acquired from a bath in the atmosphere of centuries; but these are accidents which the designer's own work cannot share, and it is just as well that their attractions should not disturb his judgment as to what is essential. All that is necessary is that the actual modelling of the object should be presented to the eye; if coloured like the original when it was new, so much the better.

As a matter of fact it is a great question whether the most important part of the work of the South Kensington Museum is not done by models of its own originals, rather than by the originals themselves. Part of its work is to send out examples to Provincial Museums and Art Schools, and though it sometimes sends originals, the greater part of these little circulating exhibitions consists of models in plaster, made by workmen, attached to the Museum, who have attained to so much skill, in colouring as well as in casting, that the copies are, for practical purposes, facsimiles. They demonstrate incidentally the possibility of improving architectural casts by the application of colour; which would, in many cases, add to their instructiveness by expressing the design more prefectly. In the case of the casts which constitute the circulating exhibitions, colour is essential as part of the design of the original or to represent its material. The works exemplified are, for the most part, textiles, book binding and leather work, wood carving, silver and other surface metal work, medals, plaster work, gesso, and other decorative handiwork. The examples already prepared are in constant circulation, and a demand in any direction is met by fresh preparations. Classes of work which are not easily reproduced by casting or electro typing, or are not sufficiently portable, are represented by photographs or coloured drawings; and there is a catalogue, 138 pages long, of books for circulation in the same manner. In addition to these the Museum has a collection of classified lantern slides on all subjects, from the composition of monumental buildings down to lace work, with catalogue numbers running to 3,000, which is available for lectures and instruction in any part of the country. The card catalogue of this collection is worth noting. Each card has, underneath the title of its subject, a print of the negative from which the slide was made, and, an application for slides for a lecture on a given subject is responded to by a set of the cards which catalogue the

illustrations of that subject; so that the lecturer can make his choice with certainty.

The special interest of these proceedings to us is that they are conducted away from London, at any distance in Great Britain or Ireland from which an application is made; and one of the directors of the Museum has expressed the opinion, not official but personal, that it is conceivable that the distance to which the material of the circulating department is sent, might be extended to the colonies. The Museum authorities seem to be always on the look out for fields for further expansion of the Museum's usefulness, and an enquiry from any bona fide Museum or School of Art in Canada would be heard with attention at any rate and might be productive.

The weak point in the situation is the absence of depositories on the other side; and, in view of the excess of advantage over cost, one wonders at it. Toronto ought to have a museum of architecture and decorative art. It is a mistake to try to go on without one; and to have one is not such a great affair after all in the way of cost. It is not necessary to have originals to do good work; and it is not necessary to have everything that can be got together. Many of the old world museums are fuller than would be necessary for us, or indeed desirable. For them there is a mixed motive. There are more critics of the past among their frequenters than creators of the future, and for historical purposes a collection cannot be too complete. But what we, in Canada, want to study is not history in design but design in history. We need only a skeleton collection, the elemental types and nothing else; but we need these if we are not to flounder about, arriving at last, if we arrive anywhere at all, only at a point from which we should have started.

A well selected collection, arranged according to subject only, ignoring history as a theme by itself, would not be too extensive either to be purchased or housed. The greater part of such a collection has already been cast, and there is nothing to prevent special castings being made to complete a sequence or scheme.

Casts of the various objects of manufacture would be for the most part inexpensive. It is architecture that costs sums to cast which require consideration; yet architecture is, if anything, more in need of models than the manufacturing arts, for its originals, while the buildings exist, cannot be transported. The cost of an architectural room may be fairly gathered from an examination of the rooms at the South Kensington Museum; for the cost of each piece that has been bought is, as a rule, printed in a corner of the label which gives the name and date of the object from which the cast was taken. The examples below are given, not as subjects particularly suitable for a Toronto gallery, but as types of size in relation to cost. Size at the South Kensington Museum runs large. They have, in casts, the whole three portals of the 13th Century Gothic Cathedral of Santiago de Compostella, in Spain, measuring 57 feet in width, covered with sculptured figures in all possible and impossible places, and costing £2,300. They have the whole of Trajan's column (the top half standing on the ground beside the bottom half); the whole doorway of San Petronio at Bologna, 51 ft. by 40 ft.; the whole of the mantel from the Palais de Justice at Bruges, including 6 or 8 feet projection of the ceiling above it. In originals, they have a Flemish rood screen 42 ft. by 30 ft. costing £900; and the timbered front of the Sir Paul Pindar house as it stood on Bishopsgate Street, except the gable. But not to consider objects of this magnitude for the beginning of a collection, here are some examples, selected as being familiar either as individuals or as types:

1. Niccolo Pisano's pulpit in the Duomo of Pisa; panels crowded with figures half detached; 8 columns resting on beasts and groups of figures; a sufficient height of the column, against which the pulpit is set, included, and the steps which go round the column. Over all about 14 ft. x 18 ft. x 13 ft. high. Cost £320.

2. Tomb of Carlo Marsuppini in Santa Croce, Florence. Elaborate 15th century work. Carved podium; niche with columns, entablature and circular pediment; 12 ft. wide by 20 ft. high over all; pair of figures at base; pair of figures on cornice; bas relief in tympanum; elaborate sarcophagus in niche, with recumbent figure on top. £210.

3. Donatello's Singing Gallery for the cathedral at Florence. Double planes, columns in front of figures; about 18 ft. by 14 ft. and 4 ft. projection. £152.

4. 13th Century Doorway from Norwich Cathedral. Jambs recessed four times with columns in front of mouldings. Enthroned figure with angels on soffit of the arch. Over all 11 ft. by 15 ft. high. £120.

5. Choir screen from cathedral at Hildesheim. Arcade of 13 arches; 12 filled each with a figure, the 13th a doorway. Smaller open arcade above. 25 ft. long by 11 ft. high. £81 10s.

6. Tomb of Filippo Decio from the Campo Santo at Pisa. Half reclining figure on top reading a book. The arms and book being partly free complicate casting. 6 ft. 6 in wide, 9 ft. high. £45.

7. Chimney piece from Hotel Lallemant Bourges, French, 16th Century. Large fireplace, carved projecting top and portion of ceiling. 12 ft. x 13 ft. £44.

8. Doorway, 15th Century Italian. Pilasters, lintel and cornice; all carved. 10 ft. 6 in. by 12 ft. high. £34 10s.

9. Portion of Dutch screen, with 5 elaborate 16th Century columns. 11 ft. x 6 ft. £9 18s.

10. Anglo Saxon cross, at least 15 ft. high, with low relief carving. £7 15s.

11. There are several valuable models to scale, of buildings or rooms. These appear to have been made to order but the cost is not attached. Models of sections of Italian buildings, decorated by painting, probably cost serious sums to produce; but possibilities are shown by a model of Fergusson's theoretical restoration of the Parthenon, which cost only 14 shillings.

Some of the Italian originals at the South Kensington Museum were got at prices which tempt one to stray from decision in favour of casts. £75 for a black marble doorway 9 or 10 ft. high, carved all over with cinque cento carving, is cost price or less; £16 for a carved stone mantel 8 ft. by 12 ft. is certainly less than cost. But buying prices are not what they used to be, and as a matter of fact these particular pieces are not such good work as the subjects in the cast room; and a cast on the same scale costs less.

If there is to be any dealing in originals, England is the country for it. There is a continual pulling down and rebuilding going on and good details find their way to dealers or to museums. The South Kensington Museum has some beautiful specimens of this kind, gifts from the owners of old buildings which were pulled down.

In fact it is well worth noting in conclusion that gifts to the South Kensington Museum far exceed in number and value, its purchases. It is also the repository of some fine collections which the owners have no means of housing themselves. At first as a nucleus, later as a recognized centre, the Museum has attracted gifts and loans, which is also instructive.

W. A. Langton.

THE FINK TRUSS BY GRAPHICAL STATICS.

By W. H. B., Berlin, Ont.

Professor Wright's solution in the March number is ingenious, and roundabout. Here is another:

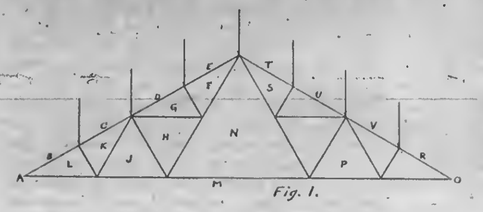

Fig. 1.

Assume a vertical load of 10 units applied at each panel point. Consider first the primary members of the truss, giving a frame of single triangulation, Fig. 2.

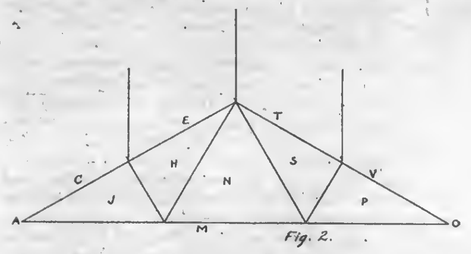

Fig. 2.

The load BC, 10, is carried 5 to A and adds 5 to CD; DE adds 5 to CD and 5 to ET; and so on. Ignore loads at A and O as they do not affect the frame. There remain loads CE, ET, and TV, 20 each. The stress diagram, Fig. 3, easily follows:

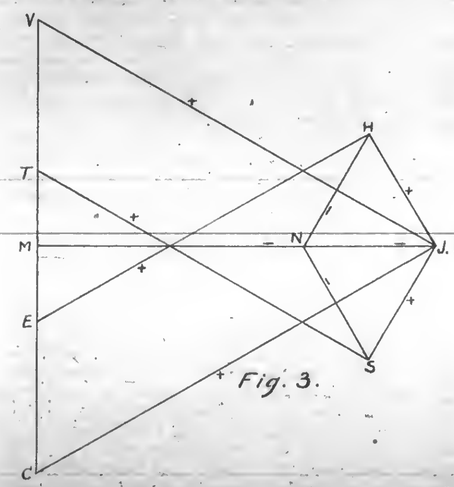

Fig. 3.

VTEC MV is the force polygon, made up of the loads VT, TE, and EC, and the two reactions CM and MV. It is a straight line because all the forces applied to the frame are parallel. Beginning at point O of the frame draw, in the stress diagram, from the ends of MV, the known force at O, the two lines VP, and PM parallel to VP and PM of the frame. The force MV, the reaction at support O, is upward. Following around the triangle in the direction given by that of the known force, VP is found to be in compression because the direction is towards O, the apex, and PM in tension because the direction is away from O. Mark these lines at once, in the stress diagram, + for compression and — for tension. Pass next to the apex SPVT of the frame, because the load VT and the stress VP are known. Draw PS and ST parallel to the corresponding lines of the frame. Both of these stresses are found to be compression. Proceed in like manner throughout the frame to the support A. For the closing line, the stress JC, the points J and C are fixed and the line must at the same time be parallel to the frame line JC Fig. 2. If the procedure has been correct this will be so. With the reaction line, CM, the operation is carried back to the point M from which it started, and the necessary check of its correctness is had.

Consider next the secondary stresses induced by transference of the intermediate loads to the main panel points. In the present case one determination only is required. Take the frame consisting of the triangles L and K Fig. 1, shown separately in Fig. 4. The supports are A and D. Fig. 5 is the stress diagram:

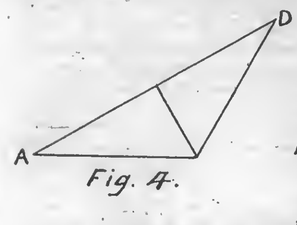

Fig. 4.

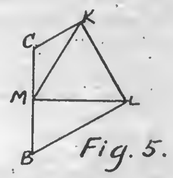

Fig. 5.

The stresses for the complete frame, Fig. 1, are obtained by adding the respective stresses of Fig. 5 to those of Fig. 3. BL Fig. 5, and CJ Fig. 3, give the required stress BL; CK and CJ give CK; BL and EH give DG; and so on. In the bottom chord the end panels only are affected by the secondary system. LK, KJ, and the similar members throughout the frame are affected by the secondary loads only, while stresses JH, HN, etc., are obtained from the assumed primary loading only.

It will be seen that this solution gives the same stresses as that of Professor Wright, whose solution would not be possible were the stresses LK, KJ, etc., due to anything else than the loads at the secondary panel points alone.

The solution given is for static symmetrical loading. The maximum stresses in a roof truss are due to drifted snow and wind pressure acting on one side only. These forces may cause reversal of some of the stresses due to static loads.

The term vector diagram is new, to the present writer at least. It may have a certain fitness in that the objective at any stage is the determination of two lines of which the directions are known. It is farfetched at best, and is an unnecessary innovation. And why deprive ourselves of the useful and expressive word "stress" which has the authority of Rankine and other foremost investigators? Professor Wright lacks a common word for tension and compression. Why interpolate "push" and "pull" when we may as well say "compression" and "tension" directly? The direction followed around the diagram governs in either case.

Some writers use — to indicate compression and + tension, on the mental association that compression subtracts from the length of a member and tension adds to it. It may be a matter of early training. The use of + for compression and — for tension has in its favor the practical, and graphically strong, argument that + is a good symbolical representation of a built compression member of a truss while — suggests a rod or bar, in tension.

THE ARCHITECT BEFORE THE LAW.*

By S. G. Archibald, Advocate.

Your President has asked me to give a course of three lectures before this Association on the subject of the Architect Before the Law, a subject as interesting as broad. It will not be my aim to cover the whole subject in detail, nor would it be possible for me to do so. I shall endeavor, therefore, to give you as complete an idea as I can, in the time at our disposal, of certain of the more important and vital questions with which architects have to deal in the daily practice of their profession, and I propose to begin with the question of the ten-year guarantee to which architects and builders are subjected.

An architect before the law is one who makes the plans and specifications for a building and who directs work, whose execution is entrusted either to a contractor or to workmen. The profession is, perhaps, the oldest of all professions. When Adam delved and Eve span, I presume Adam was his own architect; and when Noah built the ark, I presume, also, he was his own architect under the guiding hand of Providence. Since then architecture has advanced with advancing civilization and with its advance the law in respect thereto has become gradually more and more complete, more and more crystallized by commentators and judicial decisions. Our own law is that of the French law before the Code Napoleon, although that Code differs but slightly from ours on the subject.

The Architect must not only be an artist, he must be a "savant" as well. Mathematics, Mechanics, Physics, Geometry, Geology and Law must all be his in greater or less measure. For as Desgodets says, he cannot lay the foundation of a building if he does not know what ought to be observed between neighbors with regard to fences, wells, closets, cess-pools and so forth; he cannot erect it, unless he knows how he should place direct and side views, customary views and those of servitudes; and how he should place chimneys, hearths, furnaces, and galleries, and what contribution each neighbor ought to make to the mitoyen wall. He cannot cover it, unless he knows on what side and how, he must drain off the water; and finally he cannot tear it down unless he knows the precautionary measures which he must take with regard to the neighbors, who are always ready, at the least fault, to seek reparation from the proprietor. He might have added, that without some knowledge of the law of privilege, he will not know how to protect himself in respect of his payment for work done upon the building. In addition to this theoretic knowledge, his artistic sense must be highly developed, while on the other hand the range of his practical work-a-day knowledge must be almost unlimited.

As I have said, we will consider this evening the question of the "ten-year guarantee." The nature of the contract entered into between the proprietor and the architect is one of "louage d'ouvrage" or lease and hire and work—a contract by which one of the parties agrees to do something for the other in consideration of a certain price. Thus the architect leases his work represented by the plans and specifications and by his time and attention if he also directs the construction. Now, as a rule, and as a matter of common law, the reception by the proprietor of work done releases the workman in respect of that particular work, in the absence of fraud on his part; but our law governing architects in this regard is found in Articles 1688 and 2259 of the Civil Code of Lower Canada which derogate from the common law and are as follows: (1688) If a building perish in whole or in part within ten years from a defect in construction, or even from the unfavorable nature of the ground the architect superintending the work, and the builder are jointly and severally liable for the loss; and 2259 says, "after ten years, architects and contractors are discharged from the warranty of the work they have done or directed."†

While at first sight this guarantee may seem to some unduly severe, yet reflection will lead to the conviction that it is a most salutary measure. In passing this law the Legislature had a three-fold object:—the proprietor was to be protected against his own ignorance, the architect and builder against their carelessness and neglect by means of this wholesome threat, and the public from the danger to which it might be exposed from the ignorance of the former and the carelessness of the latter. We thus see that not only are private interests at stake, but also public order, and this principle will be found the very fountain and source of the architect's weighty responsibility.

What structures does the Code refer to when it says in Article 1688, "if a building perish," and in Article 2259—that architects are discharged from the work they have done or directed. Taking these two articles together, the Courts in France have decided that any habitation, no matter how small, for men or animals, would be considered a building. Greater repairs, modification of old buildings which would affect the solidity of the main building, the establishment of a well, of a bridge, of a terrace wall, or of chimneys have all been held by French authors to be works subject to this guarantee. Accessory works not affecting the solidity of the structure itself, would, however, not come under this heading. The question of fact in each particular case must be decided by the Court on its merits, but this guiding principle must prevail, that there is only a guarantee in respect of immovable constructions, and where time alone will discover the defects thereof.

Now, what classes of people are subject to this guarantee? Evidently not the manual laborer who only leases his services. There is no "lien de droit" between him and the owner and his liability, if any ever attaches to him, is that of the general law, that everyone is responsible for his own fault. On the other hand, the lessor of work, whose object is an immoveable, is liable to this guarantee and these lessors are architects, builders and civil engineers. Under Article 1696, masons, carpenters and other workmen who undertake work by contract for a fixed price are subject to the rules prescribed in this section. They are regarded as contractors with respect to such work. The position of the sub-contractor has been the subject of a good deal of discussion and the French authors are divided upon the subject. Those who maintain that, as there is no "lien" between the proprietor and sub-contractor, he should not be subjected to this guarantee, have the weight of jurisprudence on their side. And indeed if this were not so the principle of public order would be violated inasmuch as persons without skill and without experience would take contracts with the sole object of sub-letting them. Such a system would result to the advantage of the careless and ignorant builder, and it would multiply litigation in multiplying sub-contracts. Generally speaking, therefore, we may say that those only are subject to this guarantee who have undertaken directly with the owner either the conduct or the construction of an immoveable or of an integral part thereof.

The architect with respect to the proprietor may occupy two different positions, and his responsibility will vary accordingly. He may only furnish the plans and specifications—or he may, in addition, direct and control the work. What then will be the extent of his guarantee where he only furnishes the plans and specifications? With regard to the plans it is evident that he can only warrant them in so far as they have been faithfully followed. His liability therefor, will only be for defects which are the necessary consequence of the plans which he has drawn or of the specifications which he has given. Supposing that for motives of economy the proprietor himself employs the workmen to execute plans furnished by an architect, and after the building has been constructed some five or six years, it threatens to fall down. The proprietor, in order to exercise a recourse against the architect would require to prove that the plans and specifications had been followed, and that the defect lay in them and not in the construction—such a defect, for example, as a weak foundation or insufficient beams, and so forth.

So also with respect to the material, the architect will only be liable for the nature of the material which he specifies, but not for the quality used by the contractor. Thus, an architect who specified wood where he should have specified steel, will be liable if the building be endangered on that account. On the other hand, if he specify a material commonly believed among architects to be proper material, he will not be so liable.

A very much more important and interesting question presents itself with respect to the architect's liability for defects in the ground, where he only furnishes the plan. This point is very much controverted. Some of the French authors and notably Lepage and Guillouard consider that the architect has no responsibility with respect to the soil, inasmuch as he may never see it, but that the contractor who is on the spot must answer alone for this. On the other hand, though this guarantee may seem almost too rigorous, there is the question of public order and safety to be considered, and the sounder conclusion would seem to be, that the architect is charged with this responsibility. The proprietor asks for a plan for a certain piece of ground. How then can the architect answer for the soundness of his plan if he does not examine the ground? How will he be able to tell of what depth his foundation should be without a careful examination of the soil? This, it seems to me, is the very first thing he should do and besides is a thing which falls specially within the sphere of his particular knowledge. Without such an examination his foundations will be the merest guess work—someone must be liable. Shall it be the contractor alone, who, as a rule, has not so special a knowledge as the architect in that respect, and who, on discovering the fault in the soil will have to come to the architect to notify him that his foundations are insufficient, and that he would do well to visit the ground in order to get some idea of what his foundation should be. Surely not. A defect in the soil is intimately connected with a defect in the plan because the plan must vary according to the soil. An error in this respect would be rather an error of conception than of execution. I am, therefore, of opinion that the architect is liable for defects in the ground even when he only furnishes the plans and specifications. It goes without saying that these defects in soil for which the architect is liable, are only such as a careful man, versed in his profession would discover upon a reasonable examination. The architect's responsibility then, is this: that he must answer for his plans, for the nature of his materials, and for the soil for which he has drawn his plans—and, of course, under the common law for his own fault which causes damage to the owner, even when the solidity of the building is not in question. If, for example, he were asked to give plans for a school capable of accommodating five hundred pupils, and after construction it was found that 300 would crowd it, he would be liable in damages for this fault. If, however, as is generally the case, the architect also direct the work, his responsibility is still more weighty. Besides, all of the obligations to which the architect who only furnishes the plans is held, he must warrant their proper execution, must see that the materials are of the proper quality and are properly used, and, generally speaking, is responsible for everything in connection with the building.

Not only, in this case, is the architect liable for defects in the soil, but he is liable for defects in construction which are only such on account of the peculiar situation of the building. Thus, for example, if the house is to be erected on a high bank exposed to heavy gales, it would be a vice of construction to roof it with slate if experience had shown that that class of roof could not properly resist heavy winds.

With respect to materials furnished by the owner, the architect is not liable unless a reasonable examination would have shown him their defective nature. If, on the other hand, they are furnished by the contractor, there can be no doubt of his liability, saving always his recourse against such contractor.

All defects absolute or negative other than those of soil or material may be called defects of construction—such, for example, as too weak foundations, insufficient dimensions of any of the materials, or a lack of proportion between the different parts so as to affect the solidity of the structure.

In addition to all this there is a presumption of defect in construction under the law, when a building threatens ruin within ten years without extraordinary reason.

But not only are the architect and builder jointly and severally liable for their own work, but they are liable where they have gone on with work already commenced by others; the architect is liable where the plans are furnished by another architect, and the builder is liable where he goes on with work commenced by another. The leading case upon the subject is that of Wardle vs. Bethune, which was carried to the Privy Council. The facts in that case were as follows (R.L. 637):—

Wardle, a builder, contracted to build Christ Church Cathedral, in Montreal, according to plans furnished by an architect and upon foundations laid by a previous contractor and approved by an architect having charge of the work. Before the cathedral was finished the tower sank and damaged the building. The cause of the sinking was found to be the insufficiency of the foundation as planned by the original architect and constructed by the former builder. This defect, though not patent, might have been discovered by Wardle. It was proved at the trial that Wardle had no knowledge of, and took no part in the testing of the soil or in the designing or planning of the building or foundation. Under these facts the Privy Council held that the builder was responsible for such defects and was not freed from liability either by acting under the direction of his employer's architect, or by reason of the fact that the defective foundations were the work of a previous builder. This judgment was a confirmation of judgments already rendered in our Superior and Appeal Courts.

The legal question was very fully gone into on both sides and a mass of authorities cited. Counsel for Mr. Wardle argued that as the foundations were not contracted for or executed by him he could not be liable for any defect in their execution nor for any defect in the soil upon which they were built. He was only bound to put the building on the foundations as they stood, and having done that properly he had no further liability. The plans and drawings were made by an architect employed by the Cathedral, and he, and not the builder, should be held liable. For the Cathedral, the case of Brown vs. Laurie, the leading case in our Courts, was relied upon and it was contended that both under the old French law and under our law the builder who constructs on insufficient foundation is liable even though he acts under the orders of his employer's architect. If the obligation to answer for the foundations is a necessary part of the obligation to warrant the stability of the building, how can a distinction be made between a builder, building on his own foundation, and a builder building on a foundation made by another builder. And if a builder is not relieved by following the directions of the architect, how can he be relieved, by the fact that the foundations were already laid, from the duty of examining them. In this case, as in all others of this nature, the element of public policy is not to be lost sight of. In rendering judgment in this case, their Lordships referred to Brown vs. Laurie, and adopted the principles there laid down.

Their Lordships, after a discussion of the case went on to state, that the broad general rule of law—the rule certain for architects and builders in the execution of the works entrusted to them—is that there is annexed to the contract, by force of law, a warranty of the solidity of the building, that it shall stand for ten years at least; that the approval and directions of a supervising architect, or his omission to ascertain the nature of the soil of the foundation, by known and available tests does not exonerate the builder from the consequences of following such direction, or of building on the foundation without making himself sure of its sufficiency.

In connection with the same building, Scott, the architect, sued Christ Church Cathedral for commissions due him. The defence was that the Church had suffered dam-

* A series of lectures prepared for and delivered before the Province of Quebec Association of Architects, 1903, and published by permission.
† In the Province of Quebec.

age, for which he was responsible, which more than offset any commission due him. Scott answered that he had faithfully followed the plans of Mr. Wills, the architect, who had first been engaged for the building, and that he was not liable for defects in Mr. Wills' plans. This pretension was overruled and the Courts laid down the principle that an architect was liable even where he only followed plans of another architect handed him by his employers.

The architect is liable along with the builder for errors committed by the latter, because he is held to see that a work well conceived by him is well executed by the builder—this doctrine was illustrated in a case of McDonald vs. David, 14 L. C. R., 31. In this case the floor of a building on St. James street had sunk in consequence of the insufficiency of the timbers used to support the joists. It was there held that the architects, as well as the carpenters and joiners employed in the erection of the building, were jointly and severally liable for the damages incurred.

It was held in a case of Cowen vs. Evans that where a contractor undertakes certain works for the proprietor of a building for a certain price, independently of the other contractors, and not having the general direction of the works, he is not liable for the faults of the other contractors. In this case Cowen put a brick wall on the stone foundation of another contractor; after his wall was up some way, he found defects in the foundation, pulled down his wall, and sued for annulment of the contract. He was answered that he had accepted the foundation and was responsible for it. This plea was dismissed, the Court rendering judgment in the sense just quoted. The architect must also warrant that he has not violated any of the municipal regulations or any of the laws of neighborhood. Thus, if a mitoyen wall be pierced without the neighbor's consent, or if a chimney hearth be placed directly over beams of wood, or if a well be dug near a neighbor's wall without any counter wall being provided for, in all this class of cases the proprietor could recover not only the damage to his own building but whatever he may have been compelled to pay his neighbor for damage done to him. The architect must build so as to leave no room for any complaint on the part of the neighbors. This guarantee must be distinguished from the guarantee of solidity on the part of the architect, from which he is relieved after ten years. Under Article 1053 of our Civil Code, everyone is liable for his own fault which causes damage to another. Prescription, therefore, of this action will only begin to run against the owner from the moment when he had knowledge of it and would not be acquired in favor of the architect for 30 years from that date. This, at least, is the opinion of the majority of the authors, though Duvergier, Troplong, Fremy-Ligneville and Perriquet consider that it is prescribed in ten years—and is in the same position in that respect as the guarantee with respect to solidity. This, however, is hardly a question of practical utility. It will be time enough for you to discuss it, when you are actually troubled with it. If a fire were caused through a beam, placed underneath a hearth, becoming ignited, the action against the architect would lie from the moment of the fire whenever it occurred, and would only prescribe by thirty years. The guarantee of solidity, on the other hand, only lasts for ten years, because the law has fixed this as an arbitrary period after which the building will be presumed to have fallen through some other cause than a defect in construction. The practical effect of this is, that a defect which doesn't threaten the ruin of the building for ten years is no defect at all.—Even should the whole edifice crumble to the earth in its eleventh year, yet would there be no liability on the architect's part, if no fraud is alleged against him. Not only is there a presumption that the building was properly constructed; there is more, there is an actual bar to any action on the part of the proprietor, who will not be admitted to prove, even out of the mouth of the architect himself, that there was any defect in construction. Questions of guarantee, however, are of no importance the moment fraud is alleged. Everyone is liable for his fraud. If, for example, you have purported to build a stone wall three feet thick, but have in reality filled in the centre with rubbish and have merely put on a stone facing, you could not possibly hope to be discharged in any other way than by thirty years without action on the part of the owner from the date of the discovery of the fraud.

We have seen that the architect under the law is liable for every derogation from the principles of his art and for every infraction of the rules and laws which, as a professional man, he ought to know. Can he, by contract with the proprietor, rid himself of this weighty burden of responsibility? What if, when he has pointed out to the proprietor the defects in the soil or in the material or in the plans furnished him, the proprietor insists on his proceeding and contracts to relieve him from the guarantee imposed upon him by law. What then is his position? A glance at the principle in virtue of which this responsibility is placed upon the architect will give us the answer. Public order and safety are concerned, and private individuals cannot by contract derogate from that which concerns public order. The architect is not relieved in such a case and his duty to himself and the public is to refuse to proceed with the work. It, of course, goes without saying that he is not responsible towards the proprietor who has so released him, but he would be towards third persons damaged in any way by the ruin of the building.

It is often important to establish the exact day from which this guarantee will begin to run, and this will be from the date when the work was received. It will always be safer to have this fact fixed by a writing. All doubt upon this point will then be removed and the interest of both proprietor and architect better served. The question of prescription of this action has some theoretic interest, but is not of practical importance for the moment. It is contended on the one hand that the arbitrary term of ten years puts an end to any action against the proprietor even though the building have fallen down within the ten years. In other words, the owner must sue the architect before the ten years have expired. On the other hand it is argued that the fall of the building within ten years only gives rise to a right of action, which right will only be prescribed by thirty years, and this latter view seems to me the more sound of the two. The question of burden of proof with respect to this guarantee is a most interesting and important one. Does article 1688, when it says that the architect and the builder are jointly and severally liable for the loss, if the building perish within ten years from a defect in construction or from the unfavorable nature of the ground, mean that they will be held guilty until they prove themselves innocent, or does it simply bind them for ten years, when without that article they would have been discharged by the reception of the work? It can readily be seen how vitally this question interests the architect. Who must prove his case—the plaintiff who demands damages or the architect, who says "I am not responsible?"

At common law the reception of the work would discharge the workman. The proprietor has had an opportunity to examine it; has examined it and has received and paid for it, and the workman's responsibility ceases. But in this case Article 1688 specially derogates from this principle and says "architects and builders must guarantee their work for ten years." The French authors are very much divided upon this question. Troplong, Duvergier, Guillouard and Laurent argue that fault is not presumed and that all Article 1688 intended was to carry the architect outside the common law which would have liberated him from the moment his work had been received by the proprietor. These are onerous sections and must be interpreted strictly and the very fact of the reception of the work creates a presumption that it was well done. The article does not say that they are presumed to be in fault, it simply says that if the defect exist, they are liable for it. They argue, therefore, that the proprietor, plaintiff, in responsibility, must prove the fault which he alleges.

On the other hand, Marcade, Fremy-Ligneville, Aubry and Rau and others consider that until the architect clears himself the damage caused will be presumed to be caused by his fault. This contention has the advantage of being supported by the jurisprudence in France. In my opinion, it is the correct solution. A building which falls down can only do so through defect of construction, material, or soil, or on account of some extraordinary event which could easily be established in proof. Now the architect for ten years must guarantee the building against all these causes, save the last, and it will be perfectly easy for him to make affirmative proof of any fortuitous event which may have caused the ruin, and if he can't do this, he is liable.

If this were not so, you would force the proprietor to make negative proof; because, if he must prove that defects of construction caused the ruin, he must prove the particular defects, and this, in cases where the building had fallen down, might be very difficult proof, indeed, for him to make. He would often be forced to attempt to prove that nothing else could have caused the ruin, forced to go through a process of elimination, in fact forced to make negative proof. I do not believe that that was the intention or the spirit of the law. As I have already said, the Legislature in placing this heavy responsibility on architects and builders, did so because public order and public safety were involved. Architects and builders must, at all cost, be thoroughly alive to the importance of building well and safely, and that is why this salutary burden was placed upon their shoulders. The building must stand for ten years, or the architect must show good cause for its not doing so. While this interpretation may not be in accordance with the exact wording of the Code, yet I do think it is in accordance with its spirit.

The Privy Council in the case of Wardle vs. Bethune already cited, while not called upon to pass upon this point, gave expression to the opinion that the onus would be on the builder in the circumstances under discussion.

It is hardly necessary for me to say that this liability of the architect or builder for the whole amount of the damage suffered, has only reference to the proprietor and that as between themselves each is liable for his own fault. Thus the architect would alone be liable for defects of construction depending solely on defects of plan. On the other hand the builder would be alone liable for his own mistakes, where the architect had only furnished the plan. Where the architect has also directed the work, each is liable for his own fault. The builder would not be received to set up the negligence of the architect with respect to a fault committed by himself. As regards third parties Article 1688, which we have been discussing, would have no application. The architect's responsibility towards them would be governed by the general law contained in Article 1053, that every one is responsible for his own fault which causes damage to another.

We have seen, therefore, gentlemen, that you are under a serious responsibility to look to it that the buildings you erect are solid and built according to the rules of the profession to which you belong, and further that you cannot liberate yourself from this burden even by contract with the proprietor, because as private individuals you cannot derogate from the laws of public order which concern all citizens and to which all private interests are subordinated.

MONTREAL LETTER.

No. I.

MONTREAL IN GENERAL.

To the student of architecture to whom the cities of Europe are beknown, some for their ostentatious splendours, others for the sake of old world charms, arrival at Montreal brings a new sensation and not one of unadulterated pleasure. Every town has its architectural character just as it has its specific odours. The best way to understand this architectural character is to arrive late in the afternoon, to feed at some famous hostelry and then sally forth into the waning light to get the general impression of things—to cross the great squares and steal around the high cathedral walls what time they stand up in all their grandeur of scale in ever deepening silhouette against a lemon sky. Daylight means details to the roving quizzical architectural eye and, details are architectural accidents whereby much good work is spoiled and little bad work is redeemed. At dusk the details are washed out and a first impression at the magic hour may be the truer as it certainly is the more lasting on this account. Unfortunately steamers which have spent the night at anchor between Montreal and Quebec are apt to arrive in the morning and after the beauties of the St. Lawrence it is forcibly brought home that "God Made the Country and Man Made the Town," and the comparison of workmanship is trying to the latter. Thus it is conceivable that the sensation above referred to may have suffered by unfair comparison and too much sunshine upon a a certain fair September day.

But to return to the general architectural character of the place, which is over theme, it must be understood that the writer finds there are many expensive buildings and some handsome ones in Montreal; there are a few really good buildings and a very few exceedingly beautiful ones, but all these are but a drop in the bucket and the average structure fronting on her streets is neither good nor beautiful—rarely sensible.

Architecture is a public art—the only truly democratic art—and a few isolated private examples however good will never redeem the architectural character of a city where the citizens dwell in ugliness. What makes the sensation above alluded to different from that produced by many other cities is the fact that there is so little decent building tradition manifesting itself. Where houses do not stand cheek by jowl they are most of them afflicted with one front and three backs and the backs are as a rule the less offensive compositions judged in pure elevation. Where houses stand hard up to each other the prevailing ideal is differentiation—this is attained by recourse to enormities in wood work with the underlying idea of a balcony as an excuse, or to crimes in zinc perpetrated with no excuse at all and a very light heart. Of material frauds—wood masquerading as stone, etc.,—there is no end. Amid these distressing reflections there is one ray of hope: this caricaturing of Architecture is only a phase in the city's development, and from its very unserviceableness will succumb the rigours of a climate (which by the way a new arrival has no right to mention.)

A little closer inspection reveals the fact that two serviceable types of plain house were evolved in Montreal a short time back and it is deplorable to think that the excellent traditions of which they are manifestations have not struck deeper roots.

There are in Montreal many plain limestone houses—some quite plain—others with a soupcon of French architectural instinct—not very sincere but quite charming. Substantial houses these are, built of fair blocks of stone with reasonable tin or iron roofs and decently proportioned chimneys and windows. There are none of them quite good enough to be worth an architectural student's trouble to make measured drawings of, but they are the best things on the streets and represent a once live local building tradition at least—the kind of tradition, that is, with which the architect must saturate himself if his work is to be indigenous at all. It is the curse of the modern house that it usually proclaims pretty clearly of what stock it comes, and hides as far as possible every hint of having been bred on the soil on which it stands. Local tradition has quite died out of the building trades in most parts of England and on this side many of the towns have not yet got the length of a tradition at all; but here is Montreal with a very excellent tradition in quet grey stone houses—and the tradition appears to have been plucked up by the roots about two score years ago, since when, chaos!—confusion worse confounded. The other type is in brick. Red brick, green shutters, white window frames, a medium pitched roof—what more can any designer want? Properly used these simple ingredients have been combined to form streets it is a pleasure to walk down, far more to live in; yet this type too has given place to the vulgarities above alluded to, and is no longer put up—nay it is being pulled down in several places at this moment.

The problem of winter glazing outside the ordinary window frames has been solved in Montreal in a more slovenly way than in other civilized cities subject to a "cool" winter. The appearance of a house depends immensely on the external window finish, and for four months of the year every house in Montreal wears spectacles which spoil the expression of eyes that might be quite pleasant. In Russia and Northern Germany the double glazing has been solved in a variety of ways, neat and handy, some of them very ingenious and all without recourse to the barbarous expedient of slapping a rough chamfered frame of inferior glass on the outer edge of the window opening.

The real difficulty which has not from its nature been better solved elsewhere is the roofing question. The slates of Montreal are very good and very ugly, and they don't improve or deteriorate with the kindly hand of time. Lead is no use. Copper goes as black as the slates. The good old tin has been out of the market goodness knows how long. Zinc and iron remain, and the genius who could give artistic expression to these obdurate and unsympathetic materials is not yet in evidence. A medium pitch roof has to be cleared of snow, a steep pitched roof is a danger to the community—a flat roof remains the best solution, but how is a building as a whole ever to look right even in the glory of evening light and growing shadows with its top shorn off and its chimneys growing like mushrooms, here and there, in a desert of asphalt and gravel?

Yes, the architects of Montreal have their little problems to solve and by degrees, if properly faced, the architectural character of the place will improve, but it is not solving the problem of designing for a flat roof treatment to put an 80° slate slip above the cornice just as an acknowledgement of the old habit of slating roofs, while a flat roof is concealed behind, nor is it any use relying on zinc "wheriligigums and whigmaleeries" to distract the attention from the drawbacks of a dull sky line.

There is a little and a very little good old work in Montreal—a closer study of it would do much to improve the present state of things.

There are a few and a very few beautiful new buildings in Montreal—and these willbe recorded from time to time by the

GARGOYLE.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.*

Address by John S. Archibald 1st Vice President.

There comes a time in the life's journey of everyone, when it is advisable and advantageous to stop and calmly survey the road recently travelled. Such contemplation may not always be pleasing for the reason that no matter what the results may have been we feel convinced that if we had to travel the same ground over again we could improve on the past and the results would be more satisfactory. Faults become apparent in the perspective of time, lost opportunities stand out strongly in vivid contrast to the background of what little has been accomplished and results which called forth extraordinary effort, seem, in the blue haze of the distance, to become pigmy and insignificant. Such are usually the first thoughts which strike us. Yet when these depressing mists have been brushed aside, we begin to see and realize the steep hills successfully travelled, the may milestones passed, and here and there, the seeds sown on the journey springing up and bearing fruit according to the quality of the seed placed in in the hands of the sower. And so it is with the life of our Association. We are now entering upon the 14th year of its existence, and from the point of view of time and circumstances, I consider it advantageous to glance over our past history with a view to finding out if any work whatever has been accomplished, what that work may be, if the results obtained can be considered satisfactory and on what lines must the work continue.

The Association was brought into being on the 30th December in the year 1890, when, at that time, the Act of Incorporation was assented to by the Lieutenant Governor in Council.

I have very little to say regarding the first period of the Association life, viz., from the date of its inception up to the year 1898. At the same time, we cannot be too loud in our praise of those members of our profession who recognizing their duty to the public interests, comprehending the immense responsibility placed upon the shoulders of the followers of our profession in the Province of Quebec, and being alive to the possibility and advisability of advancing the art of Architecture by united efforts along recognized lines, bent all their efforts to obtain the original charter. These members have every right to congratulate themselves on being the pioneers of compulsory registration of architects on the Continent of America. At this late date it is difficult to realize the mightly obstacles and prejudices that had to be overcome, and when we to-day discuss this phase of the question, we are apt to forget the labour and toil which terminated in such a successful issue. Their example has been followed by the State of Illinois, and many attempts have been made to have a similar law enacted for the Province of Ontario, and I am strongly of the opinion that some of us will live to see the day, when the work begun in the Province of Quebec, will branch out and bear fruit from the Atlantic to the Pacific, and we shall have the practice of the profession recognized in law as of such importance as to merit the attention of the Legislative bodies and result in the passing of enactments similar to those under which we now govern.

It is true, that up to 1898, the work of the Association was limited in extent, but this I consider was a necessary probationary period, wherein its limited membership became alive to the scope of its usefulness, its possibilities and even its drawbacks; and even at this time it began to prove its usefulness to those of the profession who were not included in its membership, for it was often used as a shield behind which they were pleased to protect themselves. In the public eye it justified its right to exist by demonstrating on every possible occasion that it existed primarily for the protection of the public and for the fostering of art. It is not surprising therefore that when amendments to the Charter were desired in 1898, all parties recognized the right of such an Association to exist, and as a result, little or no opposition was met with.

From this period, the scope and usefulness of the Association is now enhanced and the horizon has extended.

It is on the work of this second period that I desire to dwell for a few minutes, not with a view to bolstering up a case for congratulation, but with the objects stated in the introductory remarks.

The first step that was necessary after the charter had been amended, was to perfect the organization. To the Association this was imperative, in order that full benefit could be taken of its provisions. The machinery put into the hands of the Association was complicated and required the most careful study and investigation. It was necessary that the members of the Council at that time make themselves thoroughly familiar with all its different parts, to examine its mechanism in every respect, and where possible to test it under action. This all took time, and those of you who have been members of Council during the last five and a half years, will remember the difficulties and tribulations which we had to undergo. In some respects the provisions of the Charter turned out satisfactory, but in other respects it is found to be entirely inadequate. In spite of the careful consideration that was given to its compilation, errors have been noted, omissions discovered, and in some cases what can be called by no other word than "carelessness."

In the 8th annual report, presented to the members in 1898, we read "The arduous task of the material organization is now nearly completed and the Association can congratulate itself on having secured an authority much coveted by many similar Associations and from other points of view, much more influential than ours. Not only the interests of the profession but more especially those of the public, are now protected against incompetent and doubtful practice." According to this everything appeared rosy and hopeful, but under the experience of the past five and a half years, we are forced to the conclusion that there is great room for improvement in our charter. The protection of the public, spoken of, amounts to nothing, for no matter how incompetent a man may be to practice the profession of Architecture, our charter has got no authority over him unless he designates himself "Architect." The usefulness of this designation becomes apparent when we realize the fact that buildings are going up around us every day from plans drawn by persons other than those of the profession, and yet we cannot even step in and say "nay." Even when someone does transgress the law, we are met with the difficulty that no provision has been made in our charter for naming the court in which the case ought to be tried and we are therefore open to the danger that, under certain circumstances, the Association might be mulcted in heavy damages when prosecuting. Even in the case where members, after belonging to the Association, have fallen into arrears, we find that under our charter we cannot sue them for such arrears. The time has therefore come when we should look the matter boldly in the face with a view to amending our charter along the lines of greater possibilities. There should be no difficulty in having our charter amended, that the practice of the profession would be protected instead of the mere name of "Architect" and thus make it impossible for any individual to undertake architectural work unless having undergone architectural training on the lines laid down in our charter.

During this period, the by-laws governing our Association have been amended in many respects. This arose from a closer acquaintancesh p with the work, and the by-laws governing the examinations have received much attention. This question of the examinations has at all times been a difficult one to contend with, but under the new by-laws, it is anticipated that all, or nearly all the difficulties will be removed and the work of the Examining Board made much simpler.

SECOND—DUTY TO THE PUBLIC.—The Association has at all times recognized their duty to the public and much good work has been done in this respect. We see evidence every day of the public becoming educated to a higher standard and appreciation of art and for this no small meed of praise is due our Association, for they have, by means of lectures, exhibitions, and the mere fact of the existence of such an Association, exercised a leavening effect on the public mind. In our city, the building laws were drafted by the Association, and by steady, persistent effort, have passed into law. It is undoubtedly true, that there is great room for improvement in these by-laws, yet we have established the principle and precedent that we, as a body, have a right to be heard and our views receive every consideration.

The Association should at all times keep an eye over the regulations governing the erection of buildings in the city, to protest against any tinkering that might result in depreciating their value, and at all times seize the opportunity to have them amended and improved in the public interests.

That we as a body have been considered worthy of attention is evidenced in the action which crowned our efforts in the appointment of an Architect to the Building Inspectorship of this city, and this department of the city work has graciously received any suggestions from the Association, made in the interests of our profession or the public.

It is more directly in the public interest that legal proceedings were taken against those persons who violated our charter.

*Delivered before the Province of Quebec Association of Architects, March 15th, 1904.

This work has always been done in a quiet way, and it is no doubt from this fact that much of the criticism has arisen, but the Council have always felt it incumbent upon them to perform this part of their duty with as little noise as possible, recognizing the fact that this part of the work of our Association, while being a necessity, does not redound to the glory of our profession. It is often said that the Association does little or nothing respecting the taking of legal proceedings against offenders of our Charter, yet in one year alone, eleven actions were entered and no year has passed which has been free from some action or other, but whereas we are a liberal profession and as such should be imbued with the highest ideals, legal proceedings are never entered, and I hope never will be, unless all other means possible fail to bring about the desired result.

Efforts have also been made to safeguard the public interests in other respects. Efforts have been made to establish a precedent, and in fact to make it law, that when any public buildings are to be erected by either Federal, Provincial or Civic Government, that means should be adopted to call forth the best that the profession can produce. It is to be regretted that we have not been more successful, but yet we must not give up the struggle; we must persevere, and some time, when we least expect it, our continued knocking may be heard.

THIRD—EDUCATION.— One of the duties laid down in the preamable of our charter, states, that it is "Expedient to insure a standard of perfection in the present practice of our profession in the province of Quebec." We think that considering the age of our Association, this duty has been well recognized. The work has been of the first importance and has taken up a considerable amount of the Association's time. It may not have resulted in all that might be desired, but there is nothing perfect under the sun, yet there is cause for congratulation. The recognition of the necessity for proper architectural education is one of the paramount causes of our being, and while the work must necessarily be arduous and require much painstaking, it must not be shirked.

Being empowered by the charter to make it compulsory for all students to pass certain examinations before being permitted to practice, the Association acknowledged it as their duty to place before these students such information as would be necessary for them to acquire before presenting themselves for examination. As a result, our library has been greatly enlarged and now contains many useful and valuable books. These are being added to from time to time and before many months have elapsed, our library will contain all of the books suggested as authorities to be studied in the pamphlet regarding examinations. Of course our purchases, in this respect, are limited to the amount of money at our disposal and this is very limited indeed, and recognizing this fact, your Association made arrangements with the authorities of McGill University, whereby the Architectural Library of this seat of learning was thrown open to members of our Association. This is a valuable acquisition, and the members should show their appreciation of such liberal consideration by exercising their right of membership on every possible occasion. Our Association has also exercised some influence over architectural education, as taught at McGill, the authorities of which have at all times received our suggestions with kindest consideration and have profited by them on every possible occasion.

In the recognition of our duty to the cause of education, a scheme of scholarship has received the attention of the Council for nearly two years and has now become an accomplished fact, and we trust that by the time the term of scholarship has ended that means will have been provided for following it up with a travelling scholarship.

We might also point out the connection that has been established with the R.I.B.A. of England, that well known pioneer of collective effort, and as a result of the efforts of some of our members, it is now made possible for anyone to present himself for their examination in our city.

Still, in spite of all that has been done regarding education, I will admit, that if we are to live up to our ideals and to our duty we have to go much further. As the Association is dependent upon the ranks of our students and draughtsmen for its coming practitioners, we should endeavor to inculcate in their minds such feelings of self-interest and good fellowship as will make them aspire to the ranks of our membership. As a parent body, we must take an interest in their educational welfare and we should therefore endeavor to bring them together in our rooms, to bind them together by some junior Association and to undertake courses of systematic lectures. The Association should also be jealous of their right and opportunities given them to educate the public in the art of Architecture.

Courses of public lectures should be given at stated intervals and thus interest the public in the possibilities of our art with a view to a higher appreciation in their own particular case, and eventually bring a stronger force of public opinion to bear on the problem of the architectural improvement of our own city.

FOURTH—MUTUAL IMPROVEMENT.—The duty of the Association to its own members has not been overlooked and I expect that it is under this title that we will encounter the greatest criticism. The success or otherwise of the Association in this respect, depends entirely upon the point of view of the critic. Some criticise as if the question of our Professional Tariff was of the first and vital interest. Others are ready to judge the value of the Association by the number of legal proceedings that have been taken against offenders, while a few believe that our first duty is to the public. They may all be right in their way, yet it is my humble opinion that we are formed into an Association, first, for the public good, and second, for the good of the profession—and the majority of the profession at that—and judging by the work of the past Councils, I am not alone in my belief. After several attempts our tariff was at last amended and passed by the Lieutenant-Governor in Council. You are thoroughly familiar with the facts of the case and it is useless now to repeat them. True, it was not the tariff that was passed by the Association, but I for one will frankly admit that I would rather have it than none at all, for at least we have the principle accepted and established that architects have a right to a Tariff that will be accepted at law. To my mind, the tariff as amended is a standing lesson to architects to be more business-like in their methods. Who among us, would give out work amounting to any considerable amount, unless the contractor is tied hard and fast by a written contract. In the name of common sense therefore, why should not all architects be compelled to enter into a written contract with their clients so that all possible future difficulties would be removed at the outset. It may be that the neglect arises from the feeling that it might be awkward to place the question of commission before the client at the outset, and hope that he will take this for granted and that matters, in this respect, will run along their own smooth course. No one is compelled to work for three or four per cent., even although such amount be stipulated in the tariff. Suppose you are offered work at 3 per cent. would you accept it? (Let us hope not.) Then on what different basis are you when the legal tariff places the commission at 3 per cent. It merely amounts to this, that it is your duty to yourself and to the profession, to inform your client, that where such a clause becomes operative, that you require a written agreement for the full professional charge. Surely you are not going to allow the law to dictate the value of your services. You are the best judge as to what your services are worth, and tariff or no tariff, your self respect should be the best judge as to what commission would remunerate you for the services rendered. Do not suppose for a moment that even if the legal tariff was satisfactory that the problem would be solved. There is nothing to hinder an architect working for less; it is purely a matter of conscience; you cannot make men honorable by law and you cannot lay down by statute that no man shall be allowed to work for less than the stipulated amount. It is purely a question of labour and hire. On the other hand, it is the duty of everyone in the profession to get a higher remuneration wherever possible and if the services justify it, and no stumbling block whatever will be put in the way of an architect who desires to obtain a higher remuneration for his work.

The tariff as passed by the Lieutenant-Governor-in-Council is the minimum where no written agreement has been entered into. Every servant is worthy of his hire, and if law places the minimum on any particular services, there must be some higher rate. It is therefore the duty of those who feel themselves capable of giving more than the average return, to endeavor to get a higher remuneration.

We hear much of the desired amendments to our legal tariff along certain lines, but I go further and say, that it is the duty of our Association to raise the minimum wherever possible and wherever justifiable, especially when we consider the extraordinary complexity and the knowledge required in our professional work in these later days; the tariff which was formed years ago when architectural work was of a simpler nature, is at present entirely inadequate.

A careful watch has always been kept over the interests of members in the legislature and elsewhere, and occasions have arisen when, without the help of an Association such as this, all efforts to safeguard our interests would be abortive.

Attempts have been made to reduce the period of responsibility of contractors to four years and to leave the responsibility upon architects according to the original ten year term. This was successfully frustrated.

In a case that has recently been decided in the Court of Appeals, our profession has been put under an undoubted disadvantage, and efforts are now being made with a view to having the Civil Code amended both in regard to the term of prescription for any accident that may occur within ten years and also with a view to separating the responsibility attached to architects from that of the contractors.

Efforts have also been made to foster and encourage mutual

intercourse, and with that end in view monthly meetings have been established, where discussions take place on subjects pertaining to our profession, and if the members would only realize the benefit that would accrue to them by taking part in these meetings, a better attendance would reward our efforts.

These meetings are bound to establish a friendly spirit of good will and toleration. Such a spirit is a necessity; without it our Association would be useless and but for it alone, our existence is justified.

Such is a very superficial resume of the work undertaken and accomplished during the past five and a half years. It is not all that might be desired by any means, but I have endeavored to look at the question from an unbiased point of view, and, while pointing out the good work that has been done, I am not in the least backward in acknowledging its imperfections and shortcomings.

We have been criticised on more than one occasion and on several counts. I do not question the right of any member to criticise the acts of the Association or the Council, for such criticism carried out along certain lines would result in much good. Constructional criticism is at all times beneficial, for it not only points out the evil but it comes forward with a remedy. Destructional criticism can be used to advantage, for if it does not point out the way to go, it at least shows up to disadvantage the way travelled, but what I object to is that system of criticism of the negative type that stands aloof and simply says that the Association has done nothing and that no good can be got out of it. These critics cannot evade their responsibility; they have no right to sit on the fence and arbitrarily say that we have done nothing, for if such be the case, then they are as much responsible as any member of Council, for it implies that they knew what to do under the circumstances but refrained from tendering their services. The Association at all times welcomes the member who is willing to take his share of the work, and the pity is, that there are so few who seem to realize their responsibility in the matter. The mere fact of having a Council does not remove this responsibility from the shoulders of the members, and the Council have at all times welcomed suggestions and well directed criticisms on the work.

To the criticisms that have been applied to the tariff, I have already referred, and to those who question the actions of the Association, with respect to illegal practice, I would remark, that it is not the first duty of the Association to prosecute such offenders. If such was the reason of our existence, I would heartily say "Perish the Association." It is necessary for every city to have its system of police, yet the mere necessity for having this protection is not the cause of its being. Police are necessary for the holding in check of law breakers, but the duty of the citizen is to keep the law and to foster and conserve its best interests, and so it is with our Association. Legal proceedings are an unfortunate necessity, but by no means of first importance, and in our zeal for the wellfare of our Association, we should not let this phase of the question blind us to our higher duty—to safeguard the public interests as pertaining to our work, to raise the dignity and standard of our profession and to foster that "Esprit de corps" without which our efforts would be abortive and valueless. Did we obtain the charter in order to prohibit certain individuals from practicing or to obtain a tariff satisfactory to all minds? If such was the idea of the founders, why was it not expressed? It was not expressed, simply because such matters were recognized as mere incidents. The organizers of the Association had a higher idea of their responsibility and in the fulfilment of that responsibility, they had to sink everything that appeared personal or mercenary. What does the preamble of the charter of the Association say? "Whereas it is deemed expedient for the protection of the public interests in the erection of public and private buildings—and to insure a standard of efficiency in the persons practicing the profession of Architecture." Analyze this clause and we find that the charter was granted, first, because it was deemed expedient for the protection of public interests; secondly, to establish a standard of efficiency, or in other words a recognition of the necessity for professional education; and thirdly, with the object of advancing the art of architecture. And again the Association was incorporated, according to the second clause of the preamble, for the object of the "acquirement and interchange of professional knowledge amongst its members, and more particularly the acquisition of that species of knowledge which shall promote the artistic, scientific and practical efficiency of the profession of architecture." In the face of such high and dignified ideals, does not the criticism of mere incidents seem trivial, and the laying of emphasis on such questions as tariff and legal proceedings, appear selfish and mercenary?

Do not misunderstand me—I do not say that we should not prosecute persons practicing illegally, or that we should not make a serious endeavor to amend our tariff, but I do say that such questions are not of the vital importance some would have us think, and, I am sometimes afraid, that in laying too great stress on these questions, we may lose sight of greater opportunities to do good, and in the effort to catch the shadow, lose hold altogether of the substance.

In my remarks on the work accomplished, I suggested the lines along which the future work lies. We cannot and must not remain stationary; we must go forward accepting our self imposed responsibilities with feelings of thankfulness and in the full realization of our duty; seize hold of the opportunity given us to advance the interests of our profession in this fair Dominion as a whole, and in the section known as the Province of Quebec in particular. But this can only be done by and with the help of every individual member of the Association. But how can this be done? By the fostering of that "Esprit de corps" which is a primary necessity, where persons are brought together to act collectively for a given purpose, and I think that you will all grant there is room for improvement in this respect.

This will hardly be disputed by anyone, on the general aspect of the question at any rate, although at the same time it is gratifying to acknowledge instances are by no means uncommon where we have received nothing but the most considerate treatment at the hands of our confreres. Yet we must admit that these instances are far too uncommon, and where it ought to be the rule it is more often the exception. It is not where we have direct intercourse with one another that the want of "Esprit de corps" is most felt, for then our self respect compels us to act so that our motives are not open to question, but it is on occasions where our actions may remain undiscovered; when nothing but brotherly consideration and common fairness should determine our course, and when the hope of personal advantage must be weighed in the balance against our duty to our confrere, it is then that we deplore the dearth of that spirit which ought to imbue the disciples of that world-old profession, which is our's by adoption. The want of brotherly feeling is in evidence on all hands. We see it in the petty jealousy which questions the public encomiums bestowed upon a confrere. We see it in the refusal to acknowledge any good work done unless it is done by ourselves. We see it in the willingness to accept work at any commission so long as we can prevent it entering another office, and we see it in the avidity with which we rush to throw our services at the feet of any one whom rumour credits with the intention to build. How can we expect sincere individual effort for the advancement of our profession and art under such circumstances? We are arrayed one against another instead of working hand in hand. Still I do not consider the solution a helpless one—far from it.

There are many reasons to which we can ascribe the present condition of affairs and without going into them all, may I touch on a few.

And the first is, that we are Colonists. Now I do not use this word in any depreciatory manner, but merely to describe the conditions and circumstances under which we undoubtedly labour. I mean by this, that we belong to a country comparatively in its infancy, whose population is composed of people gathered from the four winds of heaven or of descendants of those who only a generation or two ago, made this the land of their adoption. We have consequently not yet reached the period when our people shall be knit together by the kindly hands of time and when a common tradition shall obliterate our kaledioscopic origin. We may point to our profession in the countries of Europe, and lament the want of a similar "Esprit de corps" in our own midst, but that condition was not gained in a year, neither in one hundred and fifty years. The follower of of our profession in Europe can pride himself on the fact that he is walking, humbly it may be in the footsteps of the Masters, whose names and works are held in world-wide reverence. He is imbued with that spirit of tradition which deifies the most common-place object; while we may only look back a few years to the time when the Chief's wigwam was the Parthenon of the land, or to more recent times when the standard bearer of our profession went around with his T-square made plan in one hand and his kit of tools in the other.

Again, these are the days when the spirit of personal aggrandisement permeates every action. We will never return to the days when the personal gratification, engendered by love of our art, shall be considered full value for the labour expended. Who among us to-day would be willing to give our labour for the mere pittance often grudgingly given to the old masters? It is well to recognize the fact that the world is a very poor respecter of persons, and that the "survival of the fittest" is the gospel proclaimed day after day from the house tops. In this struggle for existence, we must not be surprised therefore, if, in some instances the corners of the finer qualities of mankind become ragged; but, recognizing the force of circumstances, let us stand shoulder to shoulder, giving mutual assistance and presenting a solid front to the varied influences that in many ways threaten the very foundation of our profession.

As a remedy for the present condition of affairs, time alone will be the great antidote.

True, much can be hoped from some of the influences which can be brought into play if we only take advantage of them. One I would mention is, such schools as McGill, where, under the influences of the broadmindedness of its professors, a band of young men is being trained up under the same masters, under the same influences and in the same professional atmosphere, and, it is but natural to expect that when they take their place in the ranks of practicing architects, that their treatment towards one another and to their profession, shall be governed by that brotherly spirit which at all times is to be found amongst students having a common Alma Mater.

The second, is that power which is lying dormant in our Association, and it lies dormant purely through the indifference of the individual members.

If this Association will only use its inherent power to establish a proper "Esprit de corps" among the members, it will have justified the fact of its being. That it has the power to do so is apparent to those who are accustomed to meet here though solely on business matters. But as an Association merely, we will be powerless; it requires the assistance of every individual member, who should, in the full realization of the noble profession to which he belongs and which contains on its roll, names that stand out as beacon lights, illuminating the surrounding darkness of doubt and superstition, sink every feeling that does not redound to the glory and advancement of our profession.

BY THE WAY.

The selfishness of human nature has been exemplified by many Baltimore property owners who, taking auvantage of the demand for accommodation created by the recent fire, have raised rents to double and treble what they were formerly receiving. Short term tenants were given the alternative of paying the exorbitant rates or finding new quarters.

* * *

The difference between a municipal official who is alive to his duties and one who looks upon his position as a sinecure, is well illustrated by the results of a recent change of superintendents of buildings for the Borough of Manhattan. The new superintendent reports :—"When I assumed office there were pending, exclusive of fire escapes and unsafe building cases, over 4,000 violations. During the present quarter, 2,167 new cases have been filed, 5,237 cases have been dismissed, and 757 cases sent to the corporation counsel for prosecution, leaving pending in this office 605 violations, 500 fire cases, and 735 unsafe building cases. Cases in which the time given by the building code to the owner to comply with the law has not yet expired, and they constitute the ordinary current business of this bureau, which is receiving our daily attention."

* * *

A case was heard before Mr. Justice Gibson recently in which Robert J. Dalzell sued Miss Florence O'Mahony to recover 140l. 16s. 9., balance due for work done and materials supplied to her for building purposes. The plaintiff is a merchant residing at Killorgin, County Kerry, and the defendant resides at Beaufort, near Killarney. She by her defence denied liability, and counter claimed for 63l., and pleaded that the balance had been fully discharged, but lodged 51l. in court. It appeared that the defendant was her own contractor and clerk of works, and that she had obtained part of the materials for the building of her house from the defendant. He advised her against using a certain description of slate for the roof, but she disregarded his advice and followed her own will, and when it turned out a failure in the hands of slaters not used to it, she shifted the blame on the plaintiff. She had the house reslated, and, then counter claimed for the cost, 63l. A large quantity of the correspondence which had passed between the parties was read, among which was a post card which the defendant addressed to the plaintiff, which was in the following terms: "Deluge recommenced; mastic cement not had time evidently to harden before the rain came, and the last rain has made it as soft as putty, and is calmly soaking through. I foresee we shall spend the winter in macintoshes, come down to breakfast under umbrellas, and keep a lifeboat attached to the pump instead of a fire hose. I shall expect you to supply all the above gratis."

Mr. Justice Gibson found for the plaintiff for 124l. 17s. 9d., and allowed the defendant 10l. on her counter claim—The Architect.

Mr. John Clare, of the firm of Clare Bros. & Co., Preston, Ont., died suddenly on the 21st inst. from a stroke of appoplexy. Mr. Clare, who was 56 years of age, was very highly esteemed in the community where he lived.

NOTES.

In a recent lecture on geology in Glasgow, Mr. A. McWilliam, A.R.S.M., stated that granite consisted mainly of two minerals, quartz (hardness proportionately 6) and felspar (hardness 7), whilst the hardness of a best-quality Sheffield pocket-knife blade was 6½. The wearing powers of granite would therefore be readily understood. Pure clay with less than about 2 per cent. of potash and soda was a fireclay; if white, a china clay or a pipeclay; while containing 5 per cent. of oxides of iron and generally a fair amount of potash and soda it became an ordinary red brick clay.

A NEW FLOORING MATERIAL.

Mr. Henry M. Morgan, United States Consul at Lucerne, Switzerland, writes: Architect Siegward, of Lucerne, has patented a new system of a concrete flooring, consisting of hollow tubes of mortar and iron. It is fireproof, and will, I believe, be of considerable interest to builders in the United States.

It is claimed that this system is an improvement on the inventions of Monnier, Hennebique, Koener, and others. It consists in manufacturing, in a factory, the mortar into hollow beams for forming a floor or roof ready for delivery to the builder—one which can be laid together on the supporting walls without planking. By this means one floor after another can be laid in a very short time, and the floor so laid can be used to work upon at once without scaffolding.

This appears to me as a great advantage compared to the usual devices of stone, plaster, etc., which are dependent largely upon temperature and weather, and in all cases must be left for some days to dry before they can be walked upon.

One advantage claimed for the Siegwart system is that no workmen are required other than the ordinary laborers. Another fact which should be considered is that armored beams which are made in the building can only be depended upon for uniformity when the mortar is mixed in exactly the same proportions and when it is not influenced by shocks, frost, or rain during the time of setting. When this is done in the factory it is far easier to secure uniformity and protect the beams against weather conditions.

The beams manufactured at Lucerne have a uniform breadth of 25 centimeters (9.84 inches) and are manufactured in five sizes, viz.: 9, 12, 15, 18 and 21 centimeters (3.5, 4.7, 5.9, 7.08 and 8.36 inches) high, according to the length of span and load. The size of the iron rods in the beams is between 5 and 10 millimeters (1.96 and 3.9 inches,) and generally six such rods are used in each beam. Two of these rods are

laid parallel with the under border of the beam, and the other four are bent upward into the form of a knot at the ends in order to strengthen their holding power. The proportion of cement with coarse sand is 1 to 4. Though the beams are made hollow, they have the same supporting power as though they were solid, with a great reduction of weight. This is an important factor where freight charges are to be considered. The beams, being hollow, offer also more favorable conditions for heating. The sides are ridged, so that the cement for joining them together can enter into the vacant spaces and thus form a solid mass. The laying together of the beams is done exactly as with wooden beams.

The beams are supplied in different lengths. In Lucerne they are made up to 5.5 meters (18 feet) long; in Italy and Germany, up to 6.5 meters (21.3 feet) long; and in Russia, up to 7.5 meters (24.6 feet) long. They can be used, in addition to floors, for terraces, roofs, staircase supports, and for walls where there is side pressure, as, for instance, in coal bunkers, warehouses, etc. It has been demonstrated that with a load from four to five times as great as the normal the beams have only bent to the extent of 1 or 2 milimeters (0.0394 and 0.0788 inch). The chief advantages claimed for these beams are: Great supporting power and security from fire; they come dry and hard from the factory and can, therefore, be used at once as floors for working on; greater facility and speed in building is secured by their use; freedom from excess of heat and cold by reason of their being hollow; thickness of completed floors is reduced by their use; the beams can be used as a heating floor by sending warm air through them.

The manufacture of the beams as practiced in the Siegwart Beam Factory in Lucerne, Switzerland, and in other European countries is very simple. They are manufactured in layers of 2.5 meters (8 feet) breadth and not singly. The hollow spaces are formed by means of iron molds, around which the cement is laid and the iron rods placed in position. These iron molds are constructed so that they can be reduced in size by the turning of a screw and withdrawn when the cement has become hard. The beams are cut, before the cement has set, by means of a patent cutting machine, which can be placed in any position. Six to eight hours after laying the beams the iron molds can be withdrawn, but they are generally lett to harden for four to six days before they are separated. After two to three weeks they are ready for delivery.

There are already a large number of buildings, both public and private, in Switzerland in which the Seigwart beams have been employed, and in all the buildings now in course of construction in Lucerne they are being used. At present there are three factories in Germany, three in Russia and one in Italy occupied in manfacturing beams under the Siegwart patent.

MECHANICS' LIEN LAW.

At the recent session of the Legislature of British Columbia the addition of a number of sections relating to costs was made to the Mechanics' Lien Act of that province. The limit of fees in money or stamps payable to any judge or officer in any action brought to realize a lien is placed at $1 on every $100 of the claim up to $1,000, and this is only payable by persons other than wage-earners. The costs to the plaintiff in any action must not exceed 25 per cent. of the amount of judgment, besides actual disbursements. Where the costs are awarded against the plaintiff such costs must not exceed 25 per cent. of the claim of the plaintiff besides actual disbursements. Where the less expensive course is not taken by a plaintiff the costs allowed to the solicitor must in no case exceed what would have been incurred had the least expensive course been taken. To the costs of discharging or vacating a lien a reasonable amount of costs for drawing and registering a lien may be allowed, in addition to the costs of an action. Costs not otherwise provided for are left to the discretion of the judge or officer to whom application is made.

PERSONAL.

Mr. J. A. Pearson, architect, of Toronto, has recently returned from a visit to Europe.

Mr. A. J. Rattray has recently commenced architectural practice in Toronto, his office being in the Canada Permanent Building.

NOTES.

A striking feature of the new cathedral at Liverpool, England, will be the height of the vaulting of the nave and choir. Measured in the barrel vaulting it will be 116 feet, and in the high transepts 140 feet. No cathedral in the country approaches its height. The nearest is Westminster, the nave of which has a height of 102 feet, while York measures 99 feet; then Salisbury 84 and Lincoln 82. Chester reaches only 78. The "whispering gallery" of St Paul's Cathedral is 100 feet from the floor.

Incombustible paint for woodwork is prepared by mixing together in a fine powder 20 per cent. pulverized glass, 20 per cent. porcelain, 20 per cent. stone (silicious), 20 per cent. calcium lime. Then mix these compounds with 30 per cent. of silicate of soda. The lime gives unctuosity to the mixture, and by partially combining with the soluble glass, makes a more intimate mixture. Other proportions of the several ingredients can be used, but the percentage of silicate of soda and lime should remain as above. The mixture is applied to the surface in the same manner as ordinary paint. The first coat sets immediately, and the second may be given from six to twelve hours afterwards. Two coats are usually sufficient.

FIRE-PROOF GLASS WINDOWS

THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

OUR WINNIPEG OFFICE.

The publishers of this journal have recently opened a branch office at No. 310 McIntyre Block, Winnipeg. A resident representative has been appointed who will be exclusively employed in advancing the circulation of this journal and in keeping our readers informed regarding the latest developments throughout the west. The kind co-operation of our friends in the west is solicited in behalf of the success of this enterprise.

Publication Deferred. The demands of other matter upon our space compels us to defer to a future issue publication of a number of specially prepared articles on cement construction intended for this number.

Workmen's Compensation Act. The variety of interpretations put upon the British Workmen's Compensation Act is such that contractors are kept in a state of constant anxiety and uncertainty with regard to their liability under the Act for damages to workmen. One of the latest decisions awards damages to a workman upon whom a wall fell while engaged in eating his lunch. The fact that usually this workman went home for his lunch, and that had he followed his usual practice he could not have been said to have been injured while engaged in his usual employment, seems to have had no weight with the court.

War and Linseed Oil. A curious illustration of the many unexpected influences which may affect the prices of commodities in everyday use, is afforded by the present war between Russia and Japan. As is well known in consequence of this war the price of wheat has advanced to the highest point reached in many years. This has led to an increase in the area sown to wheat and a decrease in the area sown to flax. In the Dakotas the reduction in the flax acreage is placed at 50 per cent. As a result linseed oil, the product of flax, and the basic material of all good paint, seems destined to be high in price. This in turn will aggravate the evil of paint adulteration. with which everybody wanting to secure a good and lasting quality of work has had to contend for some years past.

Protection of Workmen. When last year the City Council of Toronto, at the instance of the labor unions, passed an amendment to the building by-laws compelling contractors to lay down temporary floors at every storey of buildings under construction, the new regulation was regarded by architects and contractors as a hardship, involving unnecessary expense and trouble. Its necessity was, however, shown by the death of a workman in Montreal the other day, who in attempting to cross from one side of a building to the other stepped on the end of a plank

which tipped, precipitating him to the ground from a height of five stories. If temporary floors had been laid down as required by the Toronto building by-law, this man's life would have been spared, and his wife and family of five young children would not have been deprived of the bread-winner. Workmen have a right to insist that every reasonable precaution be taken for their safety. The cost of necessary safeguards for this purpose should be included in contractors' estimates.

Timber Tests. A plea is made by the Engineering-Record for a continuation of the timber tests conducted some time ago under the direction of Prof. Fernow of the Forestry Department at Washington. It is very properly urged that future tests, to be of practical value to architects, engineers and builders, should deal with timber as it must be purchased from the dealer, not with selected specimens, from which much better results will be secured. On this point our contemporary says:—While engineers already possess a large amount of experimental data in regard to the resistance and durability of timber a far larger amount of information than yet secured is most urgently needed, not only as to the ultimate resistance under different kinds of stress but also a much more complete knowledge of the conditions under which greater durability may be secured. The resisting value of the details of framing, the effect of preservative processes on both elastic and ultimate resistance and a great variety of other similar data are also still lacking.

Cement Tests. With the rapidly increasing use of cement in construction work, the time has come when a systematic system of testing cement should be established. It is quite as much to the interest of cement manufacturers and dealers as to the interest of owners, architects and builders that all cement should be subjected to test. If this plan is not followed, we may expect to see failures in cement construction which will tend to weaken confidence in the material and greatly restrict its use. That there is a great deal of cement of poor quality on the market is a well known fact, and steps should be taken to prevent this material from getting into works of construction. A Canadian manufacturer of cement submitted a sample of his material to one of the Canadian scientific schools recently, and it failed to stand the hot test. If such was the result with a cement that may be supposed to have been specially selected for testing purposes, there is every reason to suppose that much of the cement bought and sold in the ordinary course of business is far below the proper standard of quality. In what way the testing of the material should be carried out is not quite clear. It has been suggested that the Government might inspect the material at the mills, as is done in Germany, but Governments are slow to act, and the adoption of a system might be indefinitely postponed if the Government were depended on to undertake the work. Perhaps a better plan would be for each city and town to adopt a regulation compelling all cement used within the municipality to be subjected to test. It is to be hoped that action will be taken in this direction at once, in order, as stated, that the development which cement construction is now having, may not be retarded.

Building in the North West. Probably nowhere on this Continent is there to be found greater activity in building operations than may be witnessed at present in the city of Winnipeg. Population is flowing into this city at such a rate that it is found impossible to build rapidly enough to meet the requirements for houses and buildings for business purposes. The value of new buildings erected last year was in the neighborhood of $6,000,000. This year the figures will probably reach $10,000,000. The population increased last year by 13,000, and will probably show a greater increase this year. The city directory shows a present population of 70,000. As a result of the demand for buildings, the number of architects and builders is rapidly increasing. There are at present about thirty practising architects in the city. Several eastern firms have recently opened branch offices. Building materials of every kind and skilled mechanics are in urgent demand. Fears are expressed lest the recent great fire in Toronto should interfere with the supply of materials and workmen required for this season's operations.

It is a fortunate thing for the city that, at the outset of its career several of the leading banks have erected on the principal business thoroughfare buildings which, in point of architectural beauty and substantiality, would do credit to any city. These buildings will serve as good examples for those to come after them, and will be likely to prevent the putting up of uninteresting and ugly buildings. Unfortunately, it has not been possible in the past to obtain red bricks at reasonable cost. Those manufactured in the immediate vicinity are grey and, while substantial in quality, give to the buildings an uninteresting effect. In such a bright clear atmosphere and a climate which in winter is sometimes severely cold, the use of warmer tints of color is desirable. The Dominion Bank, built of red sandstone from Lake Superior, has a very pleasing appearance, and should lead to the use of this stone in important buildings in the future. In view of the high price of stone and brick, it is probable that cement construction will become popular when a good quality of cement shall be manufactured in the Northwest. At present the material must be imported at a cost of $5.00 per barrel, which prohibits its use on a large scale.

There are many differences to be observed in methods of construction employed in the Northwest, as compared with those in the East. The severity of the climate in winter makes it necessary to give the occupants of buildings greater protection against the cold. Hollow walls and box construction for windows are prominent features. Houses are built as far as possible without projecting features, chimneys being kept inside the walls in order that as much heat as possible may be retained within the building. It has been found that a thin hollow wall is of greater service as a protection against cold than a solid wall however thick. As during the period of frost there is little or no rain, no coping is required for brick walls and chimneys, and the exterior of buildings is not subject to disintegration by alternate thawing and freezing, as in a milder climate.

ANCIENT LIGHTS.

The House of Lords has delivered an important judgment, on the question of ancient lights, which definitely settles the basis of equitable adjustment of the opposing interests, in this respect, of the owners of old buildings, and the promoters of new ones; not only in England but throughout the Empire, where the House of Lords is the final Court of Appeal.

The case was one of injury done to a tenement on one side of a street by adding to the height of the tenement opposite. The complaint was that a room on the ground floor of the complainant's (or plaintiff's) tenement was perceptibly darkened by the height added to the tenement of the defendant.

The darkening was a matter of fact which does not appear to have been disputable. On the other hand there were qualifying circumstances which excite sympathy with the defendant:—That the room which was darkened ran through to the back of the building and had no window at the back; so that it was dark in any case, and for many purposes would have always required artificial light at the back:—that the defendant's building, even when added to, was lower than that of the plaintiff. These circumstances, which to an ordinary onlooker seem to exhibit the plaintiff rather than the defendant as the oppressor, serve to show as the case, before coming to the Lords, had gone against the defendant in the Court of Appeal—how decidedly the Statute has been interpreted on the side of the non-disturbance of existing rights.

The Statute, commonly called the Prescription Act, gave a prescriptive right to light which had been enjoyed for a period of 20 years. The interpretation put upon this by the Courts has apparently been, that, if a building has received a certain amount of light for 20 years, the owner is entitled to claim that same amount of light for ever. According to the Times, this stiff interpretation has given rise to an attitude on the part of building owners that has grown from the merely self-defensive to the extortionate. The moment a building is pulled down, to make way for a larger one, the neighbouring owners placard their windows as "ancient lights"; in most cases with no other intention than to extort payment under threat of a lawsuit. They no doubt believe that they have a proprietary right to their light, which must be bought if it is to be interfered with. The effect, at any rate, has been an embarrassment of building improvement about which there has been much complaint by architects.

The history of the present case was that in its first trial (Dec. 20, 1900) the Judge found that the action failed because the plaintiff's premises would still, in his opinion, "be well and sufficiently lighted for all ordinary purposes of occupancy as a place of business." The Court of Appeal, (Dec. 20, 1901) reversed this decision on the ground that, according to the law of England, the owner of the ancient light is entitled to the whole amount of light which has ever reached his windows. The appeal was twice argued before the House of Lords—in May and in December of 1903, judgment was delivered on May 2 last.

The Lord Chancellor pointed out, in his judgment that, if the principle laid down by the Court of Appeal were to be applied consistently, towns would not grow; because any dweller on the edge of a town, who had for 20 years enjoyed free access of air without buildings near him, would be in a position to restrain any interruption of this enjoyment by the extension of buildings beyond him. Indeed under this principle, no vacant piece of ground could be built on in the city; and the rights of people to utilize their own land would be formidably restricted. The right of access to light not being a proprietary right in the light itself but only a right to its enjoyment which is common to all, he concludes that the test of the right is whether the obstruction complained of is a nuisance. That is to say, a dweller in towns cannot expect to enjoy absolute daylight any more than he enjoys as pure air, as much freedom from smoke and smell, or as little disturbance from noise, as if he lived in the country; yet as an excess of smoke, smell or noise may give a cause of action so it is in the question of deprivation of light—the question is one of degree. And the test of right must further have some elasticity that it may fit the surroundings and circumstances of each case, since these affect the amount of light required.

The Lord Chancellor having thus, by the investigation of elementary principles, endeavoured to get over what he calls "the danger of attempting to put a principle of law into the iron framework of a statute," the four other judges gave judgments to the same effect, with such further considerations as show the conclusion of the whole matter to be that a 20 year user of light acquires no prescriptive right beyond such consideration as one would think would be given by common law without the intervention of a statute; for the owner of a building of any age is declared to have no more than an equal right with the owner of the newest building near him to an amount of light, "sufficient according to the ordinary notions of mankind, for the comfortable use and enjoyment of that house as a dwelling house, or for the beneficial use and occupation of the house if it were warehouse, shop or other place of business." The owner of a new building, built on a lot previously vacant can of course only get a share of what light is going, but he is entitled to that; and nobody else seems to be entitled to any more. If there is less light going after the advent of the new building, the owner of a 20 years old building opposite must be content with the change so long as his building "retains its substantial identity." It seems therefore that an exceptional need for light in an old building cannot claim full consideration. This would be to uphold the right to an average MAXIMUM of the light that had been shed on the windows in the past; and this view, which was that of the Court of Appeal, the Lords reject. It is unfortunate for definiteness of decision in the matter that Lord Davey, who alone considers this aspect of the question in a concrete way, gives, in illustration, suppositional cases of one class only, viz., of premises converted from a purpose requiring less light to one requiring more; and he says that a man, in thus calling upon his neighbor to leave him a supply of light which is rendered necessary only by such alterations, imposes an increased burden upon his neighbor, which no man can do by any act of his own. This seems to limit indefensible claims for extraordinary amount of light to those which are made on behalf of a building which has altered its substantial identity so as to require more light. But he can hardly intend this limitation for he introduces his illustrations in the middle of an argument which, accepting

what he says "is agreed on all hands", that a man does not lose or restrict his right to light by not using the full measure of light that the law permits, asks :—"If the actual user is not the test where the use falls below the standard of what may reasonably be required for the ordinary uses of inhabitancy and business, why (it may be asked) should it be made a test where the use has been of a special or extraordinary character in excess of that standard." And he concludes that the only test of right is a fair standard which, under the title of a "supposed standard," is more than once alluded to in these judgments as having been objected to in a former case by one of the judges of the Court of Appeal whose decision in this case these judgements reverse. Lord Davey's final statement seems to be definite enough :—"I am of opinion," he sums up, "that the owner or occupier of the dominant tenement is entitled to the uninterrupted access through his ancient windows of a quantity of light, the measure of which is what is required for the ordinary purposes of inhabitancy or business of the tenement according to the ordinary notions of mankind, and that the question for what purpose he has thought fit to use that light, or the mode in which he finds it convenient to arrange the internal structure of his tenement does not affect the question. The actual user will neither increase nor diminish the right. The single question in these cases is still what it was in the days of Lord Hardwicke and Lord Eldon (whose decisions were given before the Prescription Act), "whether the obstruction complained of is a nuisance. I do not myself think that this rule is difficult of application in practice." In support of this latter statement which, as applicable everywhere, may perhaps be thought a strong one, his lordship adds :—"The experience of surveyors who are practically conversant with this matter is entitled to great respect ;" and also :—"The rule of 45 degrees is not, of course, a rule of law, and is not applicable in every case. But I agree with Lord Selbourne, 'City of London Brewery Company v. Tennant,' that it may properly be used as PRIMA FACIE evidence."

W. A. LANGTON.

MOISTURE IN WOOD.

According to M. Deploy, green wood when cut down contains about 45 per cent. of its weight of moisture. In the forests of Central Europe wood cut down in the winter holds at the end of the following summer more than 40 per cent. of water. Wood kept for several years in a dry place retains from 15 to 20 per cent. of water. Wood that has been thoroughly dessicated will, when exposed to air under ordinary circumstances, absorb 5 per cent. of water in the first three days, and will continue to absorb it until it reaches from 14 to 16 per cent. as a normal standard. The amount fluctuates above and below this standard, according to the state of the atmosphere. M. Violette found that by exposing green wood to a temperature of 212 deg. Fahr. it lost 45 per cent. of its weight, which accords with observations of M. Deploy. He further found that by exposing small prisms of wood ½ in. square and 8 in. long, cut out of billets that had been stored for two years to the action of superheated steam for two hours, they lost from 15 to 45 per cent. of their weight, according to the temperature of the steam which varied from 275 deg. Fahr. to 437 deg. Fahr. (125 deg. Centigrade to 225 deg. Centigrade).

NEW BUILDING REGULATIONS FOR TORONTO.

The City Council of Toronto will shortly take up consideration of a new set of regulations to govern the construction of buildings in that city. Meanwhile at the request of the City Architect, the Council have authorized the following amendments to the existing regulations, in order that the replacing of buildings destroyed by the recent fire may be proceeded with :—

Section 46 of the said By-law is repealed and the following inserted in lieu thereof :

"46. No building shall be erected or placed on old or new foundations, or on foundations partly new and partly old, unless the same shall be built with main walls of the thickness called for in the following tables, said walls to also comply with the other conditions as to heights and openings as hereafter specified.

WALLS FOR BUILDINGS USED AS A DWELLING HOUSE, APARTMENT HOUSE, TENEMENT HOUSE OR LODGING HOUSE.

Number of Storeys	Thickness of Walls in Inches.

Ten "	40	36	31	27	27	27	22	22	18	18	14	14

In the foregoing tables of thicknesses of walls the perpendicular distance from the top of joists in one storey to the corresponding point in the next storey is to be understood to mean not more than 12 feet in the basement or cellar, 19 feet for the ground floor, 16 feet for the first storey, and 15 feet each for all storeys above the first, except the top storey, which may have an additional five feet in height at the highest point. If any storey exceeds these respective heights the walls of such storey and all the storeys below the same shall be increased one-half brick, or about four and one-half inches more than the thickness given in the tables, and if basement or cellar walls exceed twelve feet in height they shall, if built with stone, be increased six inches in thickness, and if of brick four and one-half inches in thickness for every additional ten feet or part thereof, in excess of twelve feet.

All cellar or basement walls built of stone or brick shall be laid in cement mortar. If solid buttresses or iron or steel pillars not over 18 feet between centres, with sufficient strength to carry trusses or girders, are used, then the thickness of the walls may be reduced one-half brick, or about 4½ inches, provided, however, that no brick walls shall be less than fourteen inches in thickness in any hotel, office building, warehouse, factory or public building.

The thickness of walls specified herein and set forth in the tables for the various buildings are intended to apply to all exterior enclosing walls, and all such interior walls as may be required for the support of floors and roofs.

An increase of one-half brick or about 4½ inches in the thickness of walls shall be made in all cases where the walls support trussed roofs, and are over seventy-five feet long, and where walls for warehouses and factory buildings are over one hundred and fifty feet long, without masonry cross walls of equal height.

All non-bearing walls of buildings may be four and one-half inches less in thickness than called for in the tables, provided, however, that none are less than nine inches or one brick thick.

The outside walls, if of brick work, of all public halls, theatres, opera houses or other buildings in which the roofs or ceilings are carried on trusses or girders of a span of fifty feet or more, shall not be of less thickness from the bottom of the first or ground floor joists at the lowest point in the main auditorium to the underside of the trusses or girders than the following :

(1) If the walls are over twelve and not over twenty-five feet high, they are to be not less than eighteen inches thick.

(2) It more than twenty-five feet high and not more than fifty feet high, they are to be not less than twenty-two inches thick for the first twenty-five feet, and eighteen inches thick for the remainder of the height.

(3) If more than fifty feet high and not more than seventy-five feet high, they shall be not less than twenty-seven inches thick for the first twenty-five feet in height, twenty-two inches thick for the second twenty-five feet, and eighteen inches thick for the remainder of the height. For any increase in height over seventy-five feet, the thickness of walls shall be increased in the above ratio. An increase of four and one-half inches in thickness of wall shall be made in all cases where walls are over one hundred feet long without cross walls of equal height.

(4) In case there shall be one or more storeys built above a public hall, theatre, or opera house, such storeys being carried on trusses or girders, the thickness of walls shall be increased by four and one-half inches, or one-half brick for each two storeys or part thereof above every such room.

(5) If solid masonry buttresses are employed and placed sixteen feet or less apart, and extended to the foot of the trusses or girders, carrying the ceiling and roof, or if iron or steel pillar are inserted in such walls for the support of the superstructure, and at distances not more than eighteen feet between centres, such pillars extending to and carrying the super-imposed trusses and girders, the thickness of such walls may be reduced in proportion to the increase or strength afforded by such buttresses or pillars ; but in no case shall any such wall be less than fourteen inches thick in the top storey, four and one-half inches or one-half brick being added going downward for each storeys or for each gallery, or for each twenty-five feet in height of blank wall. If iron or steel pillars are introduced in said walls, the brick work around the same shall be bonded into that of the connecting walls, and each of such pillars shall have not less than nine inches of brick wall around it, the brick being measured from the extreme outer dimension of such iron or stee pillars.

(6) If a public hall, theatre, or opera house is of skeleton construction, and the steel framework carries the entire super imposed load of floors, roof and walls, then the enclosing walls shall consist of fourteen inches of solid brick work, with two inches of hollow tile, or four inches of hollow brick on the inside, properly bonded together, the balance of the structural parts to be protected against the effects of fire,

All walls given in the tables shall be increased in thickness or be reinforced with equivalent pilasters or buttresses when the following are the conditions :

When walls are more than twenty-five feet apart, one-half brick shall be added for every succeeding interval of twelve and one-half feet, or part thereof, of distance between them without intermediate division walls or rows of column and girder supports.

When any horizontal section section of walls shows more than twenty-five per cent. reduction of area on account of flues, openings or recesses, one-half brick shall be added for every succeeding interval of ten per cent. or part thereof reduction, provided that in walls of uniform thicknesses such reduction does not exceed fifty-five per cent. of the whole, or in masonry pier construction not more than seventy per cent. for each bay.

Wherever walls less than eighteen inches in thickness are utilized for the support of ordinary joists in buildings used for the sale, storage, or manufacture of merchandise, or public livery, boarding or in sale stables ledges four inches wide shall be corbelled out in not less than four courses, of brick for the support of such joists, and in buildings of all classes where furring strips, whether combustible or incombustible, are used on bricks walls, there shall be ledges equal to the thickness of such furring strips upon such walls, and in all cases where such ledges are built, they are to be commenced at the bottom of the joists, and are to be carried up to and levelled off at a line at least one inch above the top of the joists.

All wooden joists, beams or other timbers in the party wall of every building built of stone or brick or other incombustible material, shall be separated from the joist beam or timber entering the opposite side of the wall by at least four inches of mason work.

TIMBER IN WALLS PROHIBITED.

No timber except inside lintels, as hereinafter provided, brace-blocks, or wood brick, not more than nine inches in length, shall be used in any wall of any building where stone, brick or iron is commonly used. And the roofing in Limit "A" shall be of incombustible material. All brick walls shall be carried up on the construction aforesaid to the underside of the roof boards, whether front, rear, party or gable walls ; and all gable or parapet walls surmounting roofs of mercantile buildings shall be at least one brick and a half, or fourteen inches in thickness, and shall be carried to the full height of three feet above the roof, on a square line therewith. All the exterior walls of sheds abutting on lanes or passages other than streets shall be constructed of brick or stone, not less than nine inches in thickness.

V

Section 69 of the said By-law is hereby repealed, and the following inserted in lieu thereof :

"69. All buildings erected in terraces or rows must have one brick party wall to at least every thirty feet in length of frontage, and such party walls must be equal in thickness to that required for outer walls, and be carried eighteen inches above the roof, as before mentioned. The party walls in all semi-detached houses must be carried up close and flush to the roof boards to divide each separate tenement, and to go through the roof to every second tenement, with parapet walls."

PERSONAL

Mr. J. W. Siddall, architect, left Toronto recently for a visit to Europe.

Mr. Brydgeman, architect, late of New York, has recently opened an office in the Canada Life Building, Winnipeg.

Mr. Robert Wilson, formerly a well known Toronto contractor, is now local manager at Winnipeg for Mr. H. C. Stone, architect, and is also superintending the construction of the new Union Bank Building in that city for Messrs. Darling, Pearson & Over.

Spratt, Rolph & Chrysler, architects, have established an office in the Thompson block, Main St. Winnipeg, in charge of Mr. Chrysler. The firm have prepared plans for alterations and additions to the Commercial Club, and have also on hand a considerable amount of other work.

Mr. George Browne, one of the pioneer architects of Winnipeg, is about to retire from practice and take up his residence on the Hudson, about twenty-five miles from New York City. Mr. Browne has been a resident of Winnipeg since 1878, and has designed and superintended the erection of many of the important buildings of that city. His removal is very much regretted.

The Galt Art Metal Company, Limited, is a new concern which has recently started business in Galt, Ont., for the purpose of manufacturing architectural sheet metal material. The directors of the company are prominent business men of Galt, the manager being Mr. J. H. Hayhurst who was for a number of years manager of the James Warnock Company, Limited, and who, on severing his connection with that Company, was made the recipient of a gold headed cane by the employees.

WINNIPEG BUILDERS' EXCHANGE.

At various times during the last fifteen years organization has been attempted by contractors in the building trades at Winnipeg, but none of these was ultimately successful. The Winnipeg Builders' Exchange, organized last month, is founded on a broader basis, and we believe is destined to endure, and to serve a useful and important purpose. The Exchange has already a membership of nearly one hundred of the leading contractors and supply firms in all lines. Convenient and commodious quarters have been secured in the Rialto Block, 482½ Main St., where a number of important

Mr. E. Cass,
President Winnipeg Builders' Exchange.

meetings have already been held. The success of an organization of this kind depends very largely upon the Secretary. In Mr. W. W. Daly the Exchange have secured a most painstaking, obliging and efficient officer, who may be depended upon to do everything possible for the success of the organization. The other officers, directors and members of the Committees are

Mr. G. W. Murray,
1st Vice-President Winnipeg Builders' Exchange.

as follows:—President, E. Cass; First Vice-President, G. W. Murray; Second Vice-President, Joseph Bourgeault; Treasurer, T. D. Robinson; Sergeant-at-Arms, Alexander Irwin. Directors, E. S. Harrison, Angus Browne, W. A. Irish, D. Cameron, John Douglas, J. W. Morley, Thomas Cotter, J. A. Girvin, R. Watson, Victor Bouche, William Alsip, and C. H. Simpson. Legislative Committee, Mayor Sharpe, Chairman; William Garson, T. D. Robinson, William Irish and Wm. McFarlane. Finance Committee, A. T. Davidson, Chairman; Duncan Sinclair and Angus Browne.

Mr. Jos. Bourgeault,
2nd Vice-President Winnipeg Builders' Exchange.

Resolution Committee, A. J. Hammond, Chairman; C. N. Sharp, W. H. Fraser, W. Malcolm and A. N. McCutcheon. Membership Committee, Philip Burnett, Chairman; A. B. Anderson, W. Wilson, J. W. Wright and William Hanbury. Labor and Grievance Commitee, George Mitchell, Chairman; F. Powell, C. Gate, A. J. McMartin, C. A. Bell, S. B. Ritchie, John

Mr. W. W. Daly,
Secretary Winnipeg Builders' Exchange.

Douglas and J. H. Neil. We have the privilege of presenting herewith the portraits of the chief Executive Officers of the Exchange.

The objects of the Winnipeg Builders' Exchange, as set forth in the Constitution, are as follows:—1. To join in one Association all contractors, manufacturers and dealers of good repute doing business in the city aforesaid, whose vocation connects them, wholly or generally, with the industry of building, either as employing contractors in any branch of the building business or as manufacturers of or dealers in material used and employed in the erection of buildings or other structures, and who are not members of any Journeymen's Trade or Labor Union.

2. To establish and maintain among the individuals so associated a just and equitable system of dealing, and a uniformity in commercial usages by rules and

Ivey Building.—H. C. McBride, Architect.

regulations; to acquire, preserve and disseminate valuable information regarding the business in which they are severally engaged.

3. To procure (either by lease or purchase), furnish and maintain suitable rooms for the use of its members for meeting rooms, offices and other purposes.

4. To establish and maintain a system of adjustment of all disputes or controversies which may arise between its members or between its members and their employees and other persons, and for that purpose to act in concert with similar organizations.

One of the first subjects brought before the Exchange for its consideration was that of a uniform contract drawn up with a view of securing justice and fairness to all the contracting parties. In Winnipeg, as elsewhere, the want of such a form of contract has been keenly felt. In its absence, contractors have been obliged to consult and pay for the services of a lawyer to examine every contract which they were called upon to sign. Frequent objection was made by the lawyers to the terms and conditions of the contract, causing trouble and delay. It is the hope of the Builders' Exchange that a form of contract may be adopted which will be satisfactory alike to architects, owners and contractors, and which will do away with the difficulties which have been experienced in the past. As a united body the Exchange will also be in a position to deal with other difficulties such as inadequate transportation, delayed cars and unfair and excessive demurrage charges, labor troubles, etc. The Exchange will furnish a list of its members with their names and addresses to the architects of the city, and request will be made of the architects to furnish the Exchange with a copy of all plans and specifications for its members only. It is expected and hoped that next winter lectures and papers on subjects of interest to the members may be obtained and presented at the meetings.

Taken altogether the Winnipeg Builders' Exchange will be, as in other large and growing cities, a source of great benefit to all identified with the various building interests, and if loyally supported by the members will become, as elsewhere, indispensable.

THE TORONTO FIRE.

The accompanying photographs illustrate the class of buildings that met their fate in the recent conflagation.

Effect of the Fire on Warehouses Immediately East of the Ivey Building.
Part of a Copyrighted Photograph by Galbraith Photo Co.

Some idea of the intense heat can be had when stone fronts like this are fairly melted.

The Ivey building was saved only on account of the fire wall at the side. It is one of Toronto's modern warehouses—the front above the ground floor windows being built of New York pressed brick and trimmed with Roman Stone which is in itself a fireproof material.

WHAT CONSTITUTES BEAUTY IN ARCHITECTURE.*

By Barry Parker.

Mr. Barry Parker recently delivered a lecture (in two parts) at the Glasgow Exhibition before the International Association for the Advancement of Science, Arts and Education, under the main title of "Wherein Beauty in Architecture lies," and the sub-title of "Placing of Light and Shade, Detail, Masses and Ornament."

Mr. Parker said that he had been led to the choice of this subject by a feeling which had grown upon him more and more, year by year, that those interested in the development of the knowledge and perception of truth in art do, in their attemps to help one another, almost invariably miss what is perhaps most important. Anyone setting out to help others to a knowledge of architecture, whether it be to train students with a view to their practising it as a profession or with the aim of guiding others to some understanding of what they see, always approaches his subject from some point of view other than that of trying to show them some main principles or guiding instincts which have led to beautiful results in all styles and periods, and at all times, throughout the history of the art.

He teaches his pupils building construction; he teaches them architectural drawing; he teaches them any amount of the history of architecture, its development from style to style; or even some abstract mathematical systems of proportions, to their infinite and irrevocable loss of ability for any broader grasp. He teaches them the art of planning economically and conveniently; perhaps even the adaption of the architecture to the climatic conditions of a country, and the habits and mode of life of a race. He will probably go so far as to state that he feels this building to be beautiful and not that, but does he ever attempt to teach wherein lies the beauty of the one and the failure of the other?

Mr. Parker did not ask that the teacher should point out why the attainment of beauty lies in the recognition of this or that broad principle or æsthetic instinct; that would, he said, in most cases, be beyond what it would be fair to ask. But by a thoughtful comparison of many buildings belonging to all styles and all periods he could discover and points out right instincts, always followed, and factors always duly valued in successful work the world over—in fact, wherein the beauty of a building lies.

He went on to point out that this absence of any attempt to create a power to analyse into its constituent elements the beauty of one building, and to see what has led to the absence of beauty in another, was another characteristic of our art training today, which made for the increase of that army of copyists (incapable of the least originality) by which the progress of the art of architecture is so lamentably hindered. For he who has merely seen that one building is beautiful and another not, and has never approached either with any attempt to discover the qualities making for success or failure, will have no idea of doing anything more than reproducing what he has seen to be beautiful as slavishly as the new conditions in which he is placing it will admit. He will have no power to see that he commands the qualities which have made for success.

By means of a sketch of a window in Florence he had recently made for this purpose, and a photograph of a pulpit in Milan, and another of the Duomo in Florence, he showed how rightly to meet the differences in ornament demanded by considerations of distance from the spectator; how only vulgarity resulted from simple magnifying ornament because it was to be seen from a distance, and only irritation in the beholder by so designing that it could not be properly seen; how a truly happy result could only be got by designing ornament which was to be seen from a distance, simple but refined in detail, avoiding above all things multiplicity of different forms, that it may be easily grasped from a distance and satisfactory on close inspection.

Not the least interesting part of these lectures was that treating of the province of design in bringing into harmony the works of nature to the works of man; the province of design in introducing growing forms among architectural forms, and architectural forms among those of wild nature; the due fusing of the one into the other, and the softening of the abrupt contrast by frankly acknowledged art.

Finally, among the main principles in design which Mr. Barry Parker laid down as forming as it were the framework, he laid great stress on the following: "Everything anyone is called upon to design has certain clearly defined requirements, purposes and conditions, and the form must be given it which will best enable it to fulfil these before any other considerations may be entered upon. It is doomed to certain artistic failure if, from mistaken notions of the distates of aesthetics, it is given a form which will make it less able to perform its functions than would some other form; and the ability and inability of the designer is shown in the degree he makes it satisfactory to our aesthetic instincts, while at the same time he enables it to perform its functions as perfectly as possible." He also emphasised that its torm must at the same time be one which revealed and explained the construction; not one which attempted to conceal it.

From his want of power to analyse the beauty of his model into its constituent elements he would be certain so to adapt it to its new conditions as to destroy that beauty. Mr. Parker showed on the screen photographs and sketches of many European buildings, pointing out how the disposition and placing of the main masses of light and shade must take precedence of all other questions if beauty, and not entire loss of dignity is to result. He demonstrated the truth of this by showing various examples ot buildings where there was no massing of light and shade; the light was all broken up, and the shade was all broken up and spread in little patches and strips universally over the whole building. He went on to show that to gain beauty it was necessary there should be not merely restraint in the use of detail, and a sense of fitness in the parts selected to be finely detailed, but the right perception of the way in which the detail should be concentrated or grouped. "No truly happy effect ever was or ever can be produced where small and great are disposed universally over the whole surface of a building, and where no thought is given to the enhancing of the light parts and details by opposing them to the massive, the broad and the simple, where all parts are equally enriched, whether greatly or slightly, with mouldings,

*Abstract of a lecture recently delivered before the International Association for the Advancement of Science, Arts and Education. Reprinted from The Builders' Journal.

ornament, colouring, or in any other way, as is the case with so many modern buildings in which all enrichment is spread, profusely or sparsely as funds allow, equally over the whole facade."

He deplored the loss of power to rightly value plain surfaces, and showed by means of the lantern how much of the beauty of the work of the past resulted from due appreciation of these.

THE LIGHTING OF A HOUSE AND ITS EFFECT UPON THE DECORATIONS.

A good part of the usefulness of a house comes at night; it is then that we most generally throw open our house, so the problem of artificial lighting becomes a very important one. Many houses are ruined by bad lights. You can furnish a room ever so elaborately and make it seem quite bare by having a blaze of lights in the wrong place; you can seat your guest ever so comfortably, and make his visit a torture by having a glare directly in his eyes; and you can furnish your room ever so cooly for summer, and then heat it to the boiling point by ill-advised attempts to illuminate.

Fortunately, as it happens, one simple rule rigidly adhered to will bring you safely out of any difficulty.

The light should never shine directly in anyone's eyes. There is, perhaps, only one exception to this rule. At one's dressing table the lights are rightly left bare, for that is the place where one wants to see quite plainly, and where anything cutting off the light would be a hindrance.

Comfort absolutely demands the shaded light, and so does decorative beauty. A mild, soft light is always to be preferred to a glaring white light; and the shades of the lights are really the easiest way of successfully introducing colour into your scheme of decoration. It is possible to have various colours, but perhaps the best effect is obtained by having all the lights in a room the same colour. A drawing room with all the lights in pink may be made a delightful spot in which women look their best. Red and yellow are good colours, and increase the rich and mellow look of the room in which they are used. A library papered in green, with white woodwork, looks peculiarly restful and studious, with the somewhat old-fashioned white-lined green shades on the reading lamps.

Blue and most greens are to be avoided as giving the room and the people in it a ghastly look. The whole effect of a room can be changed by the colour which lights it.

As to the decorative difference between high and low lighting, anyone who has ever lived in a sparsely furnished room can bear witness. Light a ring of gas jets up near the ceiling, and the whole room looks barren. The ceiling itself becomes the most prominent feature of the room, and its bare expanse dominates the whole apartment. Put your lights down a little lower, and let the lights fall on your rugs and what furniture you have; let a slight dimness in the farthest corners distract too much attention from them, and you will find the room which was formerly barren will take on a comfortable, snug look.

The same rule applies to rooms which are furnished to their fullest capacity; the ceiling is not the feature to be emphasized, and high and unprotected lights are sure to bring about this result. Of course, to this rule there are exceptions. For example, suppose you are wanting to light a ballroom, the ceiling of which is so high that lights up there are safely out of the range of the eyes. The effect of spaciousness is what you want; the room is to be filled with people, and a clear general view must be possible. In such a case the hard brilliancy of uncovered lights is exactly what is needed.

And for those who can employ electricity there is also a possible lighting from the ceiling. A very successfully lit dining-room in New York has a rich coffered ceiling. In the squares between the cross-beams have been placed four flattened hemispheres of pinkish opalescent glass. Behind these and next the ceiling are electric lights, which diffuse a soft pinkish light all through the room. They are not called upon to do all the illuminating, for around the side walls incandescent lights with pink shades and on the tables candles, similarly protected, furnish light. The effect of the lights on the ceiling is very good. The ceiling itself is rich enough to stand illumination, and high enough to bring the lights out of the immediate range of the eye. But the scheme is rather elaborate, and for the simpler type of house out of the question.

There is very little to be said for the ordinary chandelier, depending from the ceiling's centre. In a hall, where it usually assumes the form of a hanging lantern, it is perhaps at its best. In other rooms it had best be removed. If this cannot be done, at least light all jets and turn them very low, rather than have a flaring jet at one side, while the rest of the chandelier is in hideous uselessness.

ARCHITECTS' FEES.

The American Institute of Architects has lately revised its schedule of minimum fees for professional practice. These are now substantially as follows:—

For preliminary studies, working drawings, specifications, large scale and full size details, and the general supervision of the work, the minimum charge is 5 per cent. on the cost of the work. By supervision is meant such inspection by himself or his deputy of work in studios, shops and on the building site, as he finds necessary to ascertain whether his drawings, specifications and directions are being carried out. If the constant presence of a superintendent is necessary, the owner is to pay the cost. For new buildings costing less than $10,000, and for furniture, monuments, decorations and cabinet work the charge is to be 10 per cent. "None of these charges covers alterations and additions to contracts, drawings and specifications nor professional or legal services incidental to negotiations for site, disputed party walls, right of light, measurement of work or failure of contractors; when such services become necessary, they shall be charged for according to the time and trouble involved." When heating, ventilating, mechanical, electrical and sanitary problems in a building are of such a nature as to require the assistance of a specialist, the owner is to pay for such assistance. The fees are to be paid in the following order: On completion of the preliminary sketches, one-fifth of the entire amount; on completion of working drawings and specifications, two-thirds; the remaining two-thirds from time to time.

Only those who have laid a sidewalk can realize the vast difference between work in the abstract and work in the concrete —Princeton Tiger.

MURAL DECORATION.*

By F. S. Challoner

Some one has well said that "all painting should decorate." Decorative painting, strictly so called, however, may be broadly defined as the appropriate filling with graceful lines, subtle or strong, light or dark, masses and harmonious colors, of spaces of various shapes and sizes which are made by the architectural lines of a building. These spaces may be either modelled in low relief or smooth, domed, vaulted or flat. They are sometimes on the ceiling, in the cove and frieze, or around the walls. In every instance they are influenced by their architectural environment. To fill all these panels with great art there are certain qualities other than the best composition, drawing, modelling and technique, that must be present in the work. These qualities which are essentially "mural" are always seen in the best decorative painting, and often are there at the expense of some of the others. One of these mural qualities is harmony. No scheme can be truly decorative unless harmony exists between it and the other parts of the building to which it belongs. To secure this, architect and artist must "pull together," so to speak. Else, though you may have good architecture and good painting, you will have a poor "ensemble." As an illustration, let me quote an article that appeared in Scribner's amongst the Art Notes for April, 1897; dealing with this very aspect of the question, and in connection with the newly decorated Library at Washington. The writer of that article goes on to say: "Many of the mural decorations considered separately are very satisfactory, but considered as a part of a whole they have often failed in conformity and harmony. This has resulted almost entirely from the lack of a systematic plan covering the whole building to be decorated. In place of general supervision there has been individual license. There is variety in it, to be sure, and so there is in a crazy quilt, but what is needed in decoration is not variety but quiescent unity, unostentatious oneness of effect. Some of the pictures not only swear at each other, but at the building generally." Continuing, the writer says: "If our buildings are to be decorated in a proper manner, a scheme of form, light and color, planned and controlled from cellar to roof, by some person or persons, would seem absolutely necessary. The true artist never yet suffered by architectural or decorative restrictions. The axiom of the whole being greater than any of the parts, is as true in art as in mathematics; and the great aim in decoration should be 'ensemble.' An 'omnium gatherum' of wall paintings, however good they may be separately considered, is not decoration."

In order, too, to be in harmony with its setting, a mural painting must, in artists' parlance, "cling to the wall." There should be no attempt to disguise the fact that the painting is on a solid wall and level surface. It must neither seem as though it were modelled in relief nor make a hole in it, but should lie quietly and flatly in its place.

A decoration, therefore, should not be stereoscopic, for the moment you introduce depth of atmospheric perspective, and focus an effect in one place only, as is done in picture painting generally, you at once do break through the wall.

A mural decoration, like a tapestry, should tell as a whole from one corner of the subject to the other. It should also be kept as simple as possible, since a lack of simplicity is disturbing and also prevents it being effective when seen from a distance as mural decorations very often are.

Now, simplicity does not mean emptiness, not a bit of it; it does not mean wholesale leaving out, but skilful leaving out.

The attainment of harmony in color is even more difficult in decoration than in other branches of painting. Color is largely governed by lighting, and in decoration every problem is a new one, as far as illumination is concerned.

Thus, pure colors, such as yellows, reds, blues and gold, which produce an admirable effect in the subdued light of some buildings, would look garish indeed in others that are well lighted.

Where artificial light is used it should be kept at a proper distance from the paintings or they will be cancelled; no pigment can fight against either gas or electricity. In this respect I might mention a couple of ceiling paintings which some of you are familiar with; they are in the front dining-rooms, upstairs, at McConkey's; they are about seven by fourteen feet in diameter, and in one of these the artist has represented the "Coming Day," and a Cupid with a torch lights the whole composition. In the centre of that panel a six-branch electrolier has been placed, and as a natural result that torch that the youngster carries does not count for much, it is quite knocked out by the electric lights. Some other form of lighting that room satisfactorily could easily have been devised, it seems to me, had the matter been given more attention by the architect, and the painting would have looked far better. Simplicity of modelling is another factor in decorative harmony—a factor of the greatest importance. Strong Rembrandt-like shadows are entirely unsuited for this class of work.

Of the evolution of mural painting through the ages to what in the fulness of time has become the splendid art with which we are familiar, its suitability as a means of beautifying the home and the place of worship; the mediums used; the choice of appropriate subjects for the various classes of buildings and rooms; the scale upon which these should be executed, and other matters connected with the execution of the work, interesting to architects, might also be touched upon, had I but a little more time. I will, therefore, proceed to take up the aspect of the question as an educational factor in the municipality. In its minor forms it is little more than a mere embellishment, but even then it helps to make life easier and pleasanter, but when it comes to be applied to the decoration of public buildings it should be significant, either symbolical or commemorative, and it has been so in all its best instances. The people of the past—Athens, Florence, Venice and other European cities felt the value of art in this respect.

* Paper read at the annual convention of the Ontario Association of Architects January, 1904.

They believed that certain benefits arose from the cultivation of beauty; that the pleasures of private life, the dignity of public life were increased thereby. It seemed only natural to such cities that the buildings which belonged to all should be the finest of all; consequently it was on the walls and ceilings of these buildings that the native artists were set to work. Go where you will among the great cities of the past and you will find these painted glories still, works which will make these cities famous and splendid for all time. Those cities made the interior of every public building beautiful. Why should not the cities of Canada? History tells us that Athens spent more money upon her art than upon her wars. And this art was the property of all; it belonged to every citizen who had eyes to see; it was "of the people, for the people, by the people." The history of the city was not shut up in libraries; it was made living upon the walls so that the humblest and least educated citizen knew its principal and worthiest events. Every one is more or less impressed through the eyes, especially so are the masses owing to their lack of imagination. "Pictures are the books of the ignorant," said St. Augustine.

To-day, I have been told, the same citizen in Paris walks around the court-yard of the Invalides, and easily gets the battles of the Republic by heart. At the Pantheon he is taught who civilized his country and who fought for it; he sees Charlemagne as civilizer, St. Louis as law giver, Jeanne d'Arc as liberator, and St. Genevieve as its patron saint. It is the same with the other civic buildings; they are all either decorated or being decorated and dignified by her leading artists, and so, whichever way he turns, he sees on the walls the figures and the stories of those who have helped him in the past and urged along the chariot of progress. In this way the modern Parisian is taught who are the benefactors of France, and when he next sees it he understands the great inscription in letters of gold upon the pediment of the Pantheon, "A grateful country to its great men."

It is the same in other cities of Europe; they have all followed the example of the people of the past, and if the pictured lessons are good for them such would be good to-day for all of us who have occasion to use our own civic buildings.

In our own municipal buildings, above the inner series of arches of the main entrance, you will see some decorative panels and over them the following words: "Hail pioneers; their names and deeds remembered and forgotten, we honor here." If you look around you won't find many of those famous men nor many of their deeds upon those walls. At present, barring the stained glass window, and the portraits, the place is but a whitened sepulchre. This should not be, for what Athens, Rome, Florence and Venice have done in the past, New York, Boston, Washington, following their example, are still doing in the present; Montreal, Toronto, Ottawa, Hamilton, London and Winnipeg, and the other cities of our fair Dominion may do in the future. If these countries thought it worth while, why not Canada? She has much to celebrate, the settlement of the country, the exploration of its rivers and lakes, the achievement of Confederation, our national industries, and lots besides.

MURAL PAINTINGS AS AN INVESTMENT.

In every country there are those who when anything new is suggested ask, "Will it pay? Is there any money in it? Is there a practical side to this celebration of national, civic, corporate and individual achievement?" Most assuredly there is. There are scores of illustrations to be cited to show that the decorations of public buildings may be of some financial benefit to a city or corporation. Everybody recognizes the immense amount of money which the artistic pre-eminence of Paris brings to her yearly in the hundreds of thousands who go to see, to study to buy. Some day, Toronto will be a great art centre, and tourists will pour into it by the hundreds of thousands too; but not until the municipality spends a little money along those lines, because visitors are attracted to a city largely in proportion to the amount there is to see there, its beauties in the way of monumental buildings and sculpture, its parks; magnificent drives; its museum and art gallery; and also the pictured history of the past that is displayed on the walls of its most important buildings.

In the 16th century one of the Popes, Leo X., I think it was, commissioned Michael Angelo to decorate the ceiling and the end wall of the Sistine Chapel, and to-day, if the money could be collected together, which has gone into copies, photographs, and the books that have been written about those decorations, how many such chapels would not the sum suffice to decorate? The same might be said of the Vatican, that was decorated by Raphael, to see which an army of pilgrims have tramped to Rome for nearly four hundred years.

Coming nearer home I might say that the Richelieu and Ontario Navigation Company had thought it worth while to spend a little money in this way in the decorations of their palatial steamers; some sketches of my own are around these walls; they thought it worth while to spend some money in that direction; as it made those boats that much more attractive. When there was nothing else to see out of the windows people required something to see inside. They have not done by any means all that is possible along those lines, they have but started.

The same might be said of some of the theatre companies, some of which have spent a little money in mural decorations, notably the Russell Theatre at Ottawa. Between acts, when the curtain is down, people get tired looking at each other—I suppose so any way—and long for something to rest their eyes on that will have a nice restful feeling in contrast to the movements on the stage. The restaurants also find it pays; you will often find quite elaborate decorations in palatial restaurants.

As for the decorative possibilities of our im-

portant public buildings, they are boundless. Surely no one needs to be told what opportunities are afforded by a great library—such as we are going to have some day, what evolution of civilization by intellectual development may be unrolled upon its walls; what celebration of every sort of literary knowledge from the scrawl of one of our savages upon bark, to the letters of Cadmus, and on to the printing press and modern book. No one for an instant doubts the possibilities of a court house, where all the attributes would show to all onlookers, the wisdom, justice and power of the law; the judgment, moderation, fortitude, clemency that govern the deliberations of a court. In banks, the history of money as a medium may find its legitimate expression; from the earliest barter of savages to the first coin, and from the first coin to the earliest letters of exchange, and so on, down through all the different developments of the interesting history of exchange. Agriculture from the time of the sharpened stake of Abraham's time down to the latest steam plow or other farm implement, might be treated in our markets.

The postoffice and railway station are somewhat akin to each other and for them I would suggest the history and evolution of transportation with all its variety and picturesqueness. Some of the railway stations in Paris are decorated, the Gar de Lyon is a notable instance; in that station there is a series of panels by good landscape men, forming panels around the buildings, of bits along the different branches of the road, by "bits" I mean those particular features in the landscape that are usually illustrated in the time tables or souvenirs given away by railway companies. Our own Grand Trunk Railway and the C. P. R. are trying to do something along somewhat similar lines, but a little more pictorial; they still cling to their framed picture, which, I think, is a great mistake. Between the waits at stations everyone naturally longs for something to look at; at present there is nothing but the time table and a few photographs of views of different parts of the country; and lithographs and show cards of steamship and other companies. How much better it would be if the architect in planning such a building took into consideration that very fact, and instead of using up quite so much marble around the base left a few agreeable spaces which could be filled with landscapes, views of cities, or the battle fields of the country, if there are any—we have a few—and a number of other features; I am sure the time would pass very much more pleasantly and a great deal faster.

When art was at its highest tide the artists' best patrons were the great corporations, the syndicates of the time. To-day, in Canada, there is plenty of room for the celebration by our corporations and industrial companies of our electrical, mining, lumbering, manufacturing, insurance and various other companies, whose history or business possess great decorative opportunities.

I do not think it would be out of place just here—I might have quoted it earlier—to read a clipping from an American newspaper which deals with Pennsylvania's new state capital. The article states that the State of Pennsylvania has determined to make the new capitol at Harrisburg one of the foremost examples of a building in which the architect, sculptor and mural painter have worked in absolute harmony. To show the magnitude of the opportunities and the liberality of the architect and of the commonwealth. The first detailed announcement of this important project involved $300,000 for sculpture and $150,000 for mural painting; the mural paintings are to be by Mr. Edwin A. Abbey, who is a native of the city, and the sculpture by a sculptor who was also born in that State, Mr. George Grey Barnard.

I think it would cause some discussion in the press if Mr. Ross and his Cabinet were to do likewise; still, there is no reason why they should not do it, and I think it would pay them to do it, as it will pay Harrisburg, in the number of people that will go to visit that town to see those mural decorations and to see that sculpture.

On mural painting as the greatest forms of painting I will now say a few words. Most people still seem to have an idea that mural painting is an inferior branch of art as compared with picture and portrait painting. This impression, however, soon passes away when they take the trouble to read art history or to seriously consider the decoration of any important surface with all its difficulties, intellectual and material.

A mere enumeration of the names of decorative artists ought to convince those who have not seriously considered the matter.

The greatest works of many of the greatest artists who ever lived, Michael Angelo, Raphael, Leonardo di Vinci, Correggio, Veronese, Tintoretto and others were essentially decorations. The landscape schools have arisen since the great decorative days of the Renaissance, therefore they had little practical part in the decorations of the past; but in a new decorative Renaissance, there is no reason why they should not play a part and a brilliant part too. For monumental public buildings it is probable that the great symbolical ideal, call it what you will, picture will remain the highest expression of mural art as in the Vatican, the Ducal Palace and the Sorbonne; but besides this and the historical picture, every other form of art finds place in decoration; the landscape and marine may be at once decorative and commemorative; the easel picture, if properly placed, properly lighted and properly hung may decorate a room even more delightfully, because more subtly, than would the finest porcelain or metal work.

Realistic portraits also would make magnificent decorations if properly panelled into walls and over mantels; this has been done in some of the "old world" buildings with magnificent results.

In our own City Hall there is an excellent illustration of how bad pictures look hung on a white wall without an architectural setting; they make nothing but a series of black holes and spots all along that corridor. That same corridor could easily have been panelled so as to have made a suitable frame or setting for the portraits of the various mayors of the city, past and to come.

NEW BUILDING REGULATIONS FOR TORONTO.

Attention is called to some of the new building regulations for the city of Toronto printed in this number. These comprise only a section of the new building by-law which it is proposed to put in operation at an early date. The city architect and city council are to be commended for having taken prompt action in this matter, thereby forestalling the erection of an undesirable class of buildings. Unfortunately a difference of opinion has arisen between members of the architectural profession regarding the new regulations which have already been adopted. The chief objection raised is in relation to the clause specifying the percentage of window openings in walls, and providing for an increase in the thickness of the walls where the percentage of openings is increased. While it is desirable that the cost of buildings should not be unduly increased, and building enterprise thereby retarded, the new by-laws should compel the construction of substantial structures capable of withstanding fire. One of the chief requisites of such buildings should be substantial brick walls.

It is gratifying to note the energy with which the burnt district is being cleared and prepared for new buildings. It is not likely, however, that all the buildings destroyed will be immediately reconstructed. Probably not more than from one-third to one-half will be rebuilt this year, and probably some will never be rebuilt. A sufficient number will be erected, however, to insure an unusually active building season; already the demand for bricks and certain other lines of material is greater than the supply. The scarcity of these materials is likely to interfere with the progress of new buildings outside of the business quarter of the city.

NOTES FROM QUEBEC.

[BY A CORRESPONDENT.]

Just at the present moment there is no great activity manifest in the building trades of Quebec The prospects, however, for the near future are very good, many of the leading architects have in hand plans for erection of new buildings, as well as the rebuilding of many old ones within the city, (mostly business houses), these in the aggregrate would form a substantial total and should mean a good wave of prosperity to the various trades concerned. The present unsettled state of "labour" is consequently causing no little anxiety, and is making itself felt in the great difficulty experienced in getting contractors to give solid quotations.

There is a movement on hand among the labour unions to open their shops and undertake contracts for its members, but this is not expected to meet with great favor, one of the strongest objections being the difficulty there would be in getting guarantee of specific performance, which is now obtainable through a substanial contracting firm.

It is hoped that the painters difficulty will be settled before the 1st May and it is generally expected that this will be the case.

Should, however, the carpenters force a strike, as is threatened, the effects may be of such a character as to cause serious loss and hindrance to this year's business, and the carrying over to another season of several of the projects on hand.

In addition to the immediate work referred to in the city itself several of the leading architects have on hand some important work for other towns and districts, many of which are eccelesiastical buildings. Any development in the labour situation, would therefore be greatly deplored as a menace to the steady run of substantial business which appears to have set in.

The project to pull down and clear away the old and unsightly buildings at the top of Mountain St. has now taken tangible form and estimates for the work are expected to be called for shortly; this will give an additional area to open space of some 4,000 sq. ft. in a fine and imposing position.

It is also in contemplation, when this is done, to erect on this space a statue in honor of Mgr. de Laval, the founder of Laval University, which is in close proximity.

The Committee having this matter in hand are now considering as to the best course to follow, whether to call for drawings to be submitted for consideration and thus select the most suitable, or to instruct an individual architect to do the necessary drawings to the committee's instructions.

The continued steady system of improving the public buildings and open spaces, which has been followed by the municipal authorities during the past ten or fifteen years is now making a marked difference in the appearance of the city and general satisfaction is expressed with the result.

BUILDING CONDITIONS IN MONTREAL.

Until quite recently it was believed that no difficulties were likely to arise this year between workmen and employers in the building trades in Montreal. This expectation has, however, been disappointed. A partial strike of stone cutters has already occurred. The painters' demand that the rate of wages be increased to 25 cents per hour and also that the working hours be reduced to 54 per week has failed. There is also difficulty on the part of the plumbers and bricklayers.

"Mandy, d'ye recollect how Henry Wiggins used to play marbles all the time when he was a little feller?"

"Goodness, yes."

"Well, he hain't got over his hankerin after 'em yit; this piece in the paper 'bout millionaires' houses say he has one of the finest collections of Italian marbles in the hull world."—Brooklyn Life.

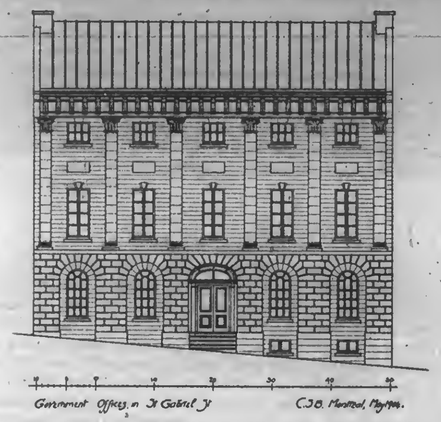
MONTREAL LETTER.

No. II.

The remarks of "Gargoyle" in the last issue called forth in certain quarters some indignation as if it had been the intention to cast a slur on the fair name of Montreal, on account of practices in architectural matters in which the men who build in these parts fail to set their faces "straight to the instant need of things" or have at least so far failed to find adequate and satisfactory solu-



Government Offices on St Gabriel St C.J.O. Montreal, Photos.

tions in the case of some of the most pressing demands of the climate—perhaps partly for the very reason that the optimistic Canadian will persist in thinking that the rigours of his climate are entirely overestimated by the rest of the world and can really be met in any old way. These off-hand ways of meeting difficulties, though they may serve their utilitarian purpose for a while, are little likely to be satisfying as a matter of art, least of all in architecture which demands before all things evidence of skillful forethought and the suggestion of permanence. Bacon's idea of art as the "adaption of the shows of things to the desires of the mind" is the golden rule that must inspire whatever of the handiwork of man is to find any lasting favor or good repute.

Though Montreal may not be a sinner above all other cities in these matters, yet the instances quoted by "Gargoyle" show that here as elsewhere we are far from any finality in the problem of meeting the case. To get our window sashes and other simple essentials efficient and at the same time satisfying to the eye is to have laid well the foundation of our architectural design. Without this the framework of our buildings may ascend to heaven but their souls will still cleave to the dust.

Some of the humbler old Montreal buildings referred to last month as exhibiting the satisfactory result of perfectly simple and at the same time perfectly unself-conscious methods of providing desirable accommodation and comfortable protection against climate are illustrated by sketches this month. They exhibit the common sense of a tradition inherited from intelligent workmen, wanting their buildings to be strong from the pleasure all men take in strength and to be comfortable because comfort was an idea that appealed to their own minds and they took a natural delight in finding themselves contributing to the sum of human happiness. At the opposite pole from these old homes stand the inanities which have been obviously considered by their builders as machines for turning coin into other men's pockets.

Amongst Montreal's old buildings however are to be found some of a more imposing air and of a public character, which whilst standing distinguished from their private and less assuming neighbors, still wear without affectation the mantle of directly inherited tradition. There is the Inland Revenue Building facing the river and there is a row of buildings in Notre Dame Street almost opposite the head of St. Lambert Hill which is quaint and pleasant. The building near the east end of St. James Street occupied by the Credit Foncier has more than a reminiscence of Adam's work. The Government Offices in St. Gabriel Street

nearly opposite the wing of the Law Courts now in progress is a fine old building.

On the last mentioned building certain young gentlemen have lately been observed hard at work in their shirt sleeves with foot-rules, tape-lines and sketch-books, and it is understood that the McGill College School of Architecture is in this way seeking to preserve an authentic record of some of the ancient land marks of Montreal and at the same time to wean its students from drawing paper, photographs and plaster casts and to introduce them to things as they are in solid fact. As the sight of the student at hand to hand grapple with his subject is usually an inspiring and infectious object lesson to aspiring minds it will be surprising if others outside of McGill do not also take up this, the most natural and most delightful introduction to the study of architecture. Montreal may not possess many monuments of a quality to repay this sort of study, yet such as they are they make this city rich indeed in comparison with others that are entirely without them. They are sufficient to give the key to unlock the treasure-house of the past for all desirous to make the history and tradition of architecture of some value to their minds, and inasmuch as they are not so very far removed in date and sentiment from the present day they are all the more within the capacity of the young student to appreciate and derive benefit from.

Whilst on the question of architectural training it should be observed that the Province of Quebec Association of Architects has just announced a Scholarship which it is offering to students. This takes the form of four years training in the course for the Bachelor of Architecture Degree at McGill University offered free to one student presumably—each year. There is nothing very formidable in the list of subjects set for examination and any beginner who should be afraid to enter the contest would do well to seek his life's amusement and instruction in some other line of life than architecture. It is a common complaint against young architectural associations that they do little for the training of the youth of the profession—the complaint in general coming of course from the somnolent and unimaginative members who fail to realize that such an association has objects to fulfil which if not more important, do at least require first attention. The Province of Quebec Association seems however to be making a beginning in this direction, and one must now look to students themselves to respond and to take some of that common interest in things which carries men so much farther than individual interest alone can do.

The revolution in the weather inaugurated on the 1st of May combined with the lapsing of old and entering upon of new leases on that date occasions a special stir amongst the building trades. Hence the time becomes a favorable one for strikes amongst workingmen. The painters, the marble cutters and the plumbers have each had their various grievances to ventilate. The plumbers alone have sharply contested the issues at stake. In these matters again the climate becomes a factor which cannot be ignored. If work is to be impeded during the coldest months of the year working hours must naturally be longer during the favorable season or the country will fail to keep abreast of her neighbors. It is only cutting according to one's cloth.

GARGOYLE II.

BUSINESS NOTES.

The new organization of the Locomotive & Machine Co., of Montreal, Limited, is making rapid headway. They have recently moved to a fine suite of new offices in the Imperial Bank building, Montreal, overlooking Victoria Square, and are now fully organized for business. Their extensive works at Longue Point are under way and well nigh completed, and are equipped for almost unlimited expansion. The whole of the structural steel for these buildings, which is of a most complete nature, was manufactured by the company themselves, and are a marvel of completeness. It is intended that while keeping the Canadian company quite separate, at the same time to keep in close touch with the American company, so that the full advantage of the experience and progress of the American concern may be secured for the Canadian company.

NOTES.

The Master Plumbers' Association of Winnipeg held their first annual dinner on the 13th inst., which proved to be a most enjoyable event.

In a recent lecture on geology in Glasgow, Mr. A. McWilliams, A. R. S. M., stated that granite consisted mainly of two minerals, quartz (hardness proportionately 6) and felspar (hardness 7), whilst the hardness of a best-quality Sheffield pocket-knife blade was 6½, the wearing powers of granite would therefore be readily understood. Pure clay with less than about 2 per cent. of potash and soda was a fireclay; if white, a china clay or a pipeclay; while containing 5 per cent. of oxides of iron and generally a fair amount of potash and soda it became an ordinary red brick clay.

A contractor with very large experience in Portland cement work, particularly in the making of walks and floors, asserts that he has never used any mixture of cement and sand for such purposes that has not been notably improved in wearing qualities by the addition of black color. Nor has he ever taken up work where black and gray tiles alternated in which the gray tiles were not inferior. When Mr. J. C. Plant finished the Phœnix building in Minneapolis with Portland cement tile floors in corridors and offices, the idea was so new as to be classed with the experiments. Red and gray tiles were used and the difference in the two is very noticeable at present, and all in favor of the colored tiles. Lampblack is generally used for coloring these tiles black, and in the absence of experience one would not predict advantage to come from its use, but so much evidence in favor of the colored tiles must be taken as conclusive.—Western Architect.

FIRE-PROOF GLASS WINDOWS

THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

OUR WINNIPEG OFFICE.

The publishers of this Journal have recently opened a branch office at No. 310 McIntyre Block, Winnipeg. A resident representative has been appointed who will be exclusively employed in advancing the circulation of this Journal and in keeping our readers informed regarding the latest developments throughout the west. The kind co-operation of our friends in the west is solicited in behalf of the success of this enterprise.

Window Glass

For a year past the window glass factories of the United States have been closed down, pending an agreement as to prices and wages. The supply of window glass has run very low, the scarcity being enhanced by the recent great fires. The present situation will probably lead to extensive importations from Belgium.

Building Conditions in the United States

The building season opened in New York this year without a strike, a most unusual circumstance. Among the causes which are believed to have brought about this condition are the serious defeat and loss of time sustained by the union workmen last year, the change of date of building agreements from the first of May to the first of January, and the less prosperous commercial conditions now prevailing in the United States.

A New Building Regulation.

An order has been issued by the superintendent of Buildings for Brooklyn which in future will compel the filing of duplicate sets of plans of all new buildings with the Building Department. The duplicate of the plans on file in the office of the Building Superintendent will be kept on the job for examination by the Inspector.

A Suggestion to Manufacturers.

Manufacturers of building materials in sending catalogues to architects would do well to enclose prices. As a rule this is not done, and architects are put to the trouble of writing for prices. We have lately received complaints on this head from some architects who could not understand the wisdom of sending out expensive literature which in the absence of prices is comparatively worthless and frequently finds its way to the waste basket.

A New Employment of Concrete

A grand stand with a seating capacity of 9000, built entirely of reinforced concrete, has recently been completed for Washington University. The area of the land is 450 x 750 feet. The seats and front and rear walls are reinforced with steel bars embedded in the concrete. The seats are supported by

cross-walls 12 inches thick at the base, 8 inches thick at the top and from 4 to 10 feet high. After the supporting walls were in position the seats and risers were built upon them in alternate sections. Careful attention was given to provide thorough drainage of the foundations. The total cost of the structure was about $32,000.

Plastering

Much of the plastering done in Toronto in recent years even in expensive buildings is of a decidedly poor quality. Notwithstanding that the cost of work in this line has greatly advanced, the modern work bears no comparison with the older examples. In much of the work now-a-days, sharp sand and hair —two of the requisite ingredients of good mortar— are conspicuous by their absence. A diligent search might reveal a little hair scattered through the mortar, but the quantity is so infinitesimal as not to have much value as a binding material. When to this is added the fact that the so-called sand employed is oftentimes little better than mud, it is not surprising that the lath and plaster soon part company.

Painters' Convention.

The recent difficulty with their employers having been settled the Master Painters of Montreal are now giving attention to perfecting arrangements for the first Annual Convention of the Canadian Master Painters' Association to be held in that city during the last week in July. Apart from the benefit to be derived from listening to papers and discussions on subjects affecting the painting business, and profiting by the opportunity of comparing experiences with others in the same line of business, master painters' who may attend this convention will receive a hospitable welcome from the local Association in Montreal and will find much enjoyment in making acquaintance with the leading commercial and financial centre of Canada.

Elevators.

The City of Baltimore has recently adopted new regulations governing the installation and operation of freight and passenger elevators. The principal provisions are that the carrying capacity of elevators is prescribed according to the area, which allows one passenger to every 400 square inches of floor space. Operators of elevators must not be under 18 years of age, and must have a certificate from an elevator company that they possess the necessary practical knowledge. The regulations provide that stairways must be separated from elevator shafts by fireproof partitions, and in the case of buildings more than three storeys high above basement, brick walls of a designated thickness are specified. All elevators are placed under the absolute jurisdiction of the building inspector.

Fire Prevention.

The British Fire Prevention Committee have hit upon a novel method for reducing the fire risk in the future. In view of the great loss of life and property due to children playing with fire, the Committee announce that, through a generous donation from a Canadian member (said to be Mr. Chas E. Goad, C.E.), it is able to offer the Committee's gold medal and a purse of £20 for the best fable for children calculated to serve as a warning against the danger of playing with matches or fire. The competition for this prize is open to British subjects residing in any part of the Empire. Elementary school teachers are particularly invited to compete. Two silver and four bronze medals will also be given as additional awards for meritorious essays. Copies of the conditions governing the Competition and all particulars can be obtained at the Committee's offices, 1, Waterloo Place, London, S.W., England, upon application by letter only enclosing a stamped addressed envelope. The Competition will close on the 31st of October next, and the awards will be announced in the leading British and Colonial papers.

MONTREAL LETTER.

No. III.

Montreal is at present looking its best in the fresh green of early summer which happily pervades all parts of the city except the docks. In many directions building operations are in full swing. The hapless remains of the old Mount Royal Club are being collected, and it will not be long before the new Club-

HOUSE ON PEEL STREET, MONTREAL.

house begins to show behind its hoarding. Messrs. McKim, Mead & White are the architects, and while it is a matter for congratulation all round that an example of that rarified classic (with all the Beaux Arts claptrap material chastely omitted), which is associated with the name of McKim, will arise in our midst, it is just a little humiliating to the profession here that the work should go to New York. True we have no one here as great as Mr. McKim, but it is a little surprising to find the Montrealers protective instincts not manifesting themselves. The fact is, art is not ruled by the usual laws of supply and demand, nor is it amenable to commercial policies—not even in this sordid commercial age, thank God! In art the supply creates the demand, which being so all things are possible. But if we pursue this vein of thought there will be no room for news, so to the next site.

The M.A.A. Clubhouse, (Mr. D. R. Brown and J. M. Miller, architects), which is situated on Peel Street, is to be completed before the end of the year, and the first brick was laid on the 4th day of June. The site is one typical of that part of the town

—sliding clay as soft as butter—and heavy piling and concreteing have had to be used. Brown uses as his artistic language that type of Helenized brick building which is rapidly becoming the venacular architecture of the States and which I doubt not

HOUSE ON SHERBROOKE STREET, MONTREAL.

the architectural students of the year 4000 A.D. will categorize as "American 20th Century."

Talking of architectural students reminds me that the McGill Architectural Department Pamphlet explanatory of the new de-

HOUSE ON SHERBROOKE STREET, MONTREAL.

gree of Bachelor of Architecture and the means of acquiring that high sounding title has now been published and copies are being sent to all the architects of the Dominion. In a sense this pamphlet is the "last word" on architectural education, for the scheme therein set forth is in substance a compromise between the training which articled pupils receive in English offices and that obtained in the American Schools of Architecture.

You will find herewith a photograph of a nice little building, Nos. 7,9,11, St. John Street, in brick and stone, which has been recently completed and also of two houses on Sherbrooke St.— Residences in plain gray limestone with dainty wooden porches painted white. For once in a way the porch order is of a scale and refinement which does not contradict the material facts of the case. The outside garb of a house is very like the outside garb of a man. In nine cases out of ten an accurate reflection of the life inside, in the tenth a beautiful swindle. Our respect is due to the man who puts up a wooden column and doesn't pretend it's made of granite, especially when the column is fair to look upon.

I also send a snapshot of a house on Peel Street. The worst we can say of it is that it's rather too consciously picturesque—like a girl, who, without being overdressed or vulgar, has put on she can stand. The materials are yellow brick with gray lime stone corbels and dressings, and the usual thin black slate of of the district, and the combination is decidedly charming, especially when the snow is on the ground. Although the pedigree of this house connects it with the Francis I period it is very

NO. 7-9-11 ST. JOHN STREET, MONTREAL.

near to Scotch work, the same toning down and "solidifying" of the volatile fancies and exubrances of the early Renaissance in France.

It is extraordinary how little direct Scots and English influence there is in the architecture of Canada. Italian, French and specialized American growths are common, but the fact that in no country in the world have the private house and the parish church attained developments comparable with the perfections to be found in England and Scotland, is not reflected in the private houses or the parish churches on this side. Readily do we yield to the French Cathedrals the first place among Cathedrals, to the Italian Palaces the first place among their kind, and to the New Yorkers the first place among the builders of skyscrapers. The domestic work and the smaller churches of England are pre-eminent among such things, and it is high time that more attention were be stowed upon them by those willing to learn from the "old fellows" what can be learned from no other source.

THE GARGOYLE.

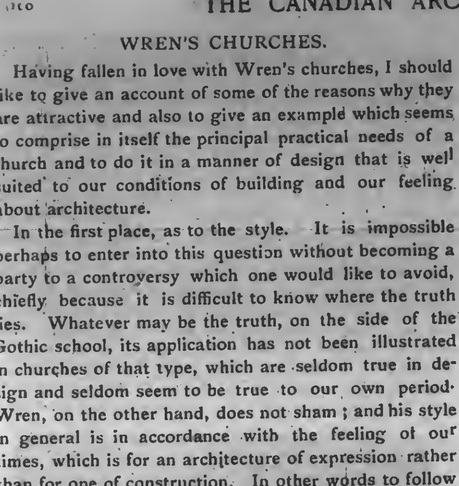
M. Auguste Choisy, inspector general in the Seroice des Ponts et Chausees, Paris, has been selected as the recipient this year of the Royal Gold Medal presented annually by the Royal Institute of British Architects.

The Society of the Beaux Arts Architects announce that they have established a travelling scholarship with a prize of $2,000 to be paid within the next two years to the draughtsman who shall become the winner of a series of competitions to be held between April 16 and July 4th. Competitors must be under 25 years of age.

WREN'S CHURCHES.

Having fallen in love with Wren's churches, I should like to give an account of some of the reasons why they are attractive and also to give an example which seems to comprise in itself the principal practical needs of a church and to do it in a manner of design that is well suited to our conditions of building and our feeling about architecture.

In the first place, as to the style. It is impossible perhaps to enter into this question without becoming a party to a controversy which one would like to avoid, chiefly because it is difficult to know where the truth lies. Whatever may be the truth, on the side of the Gothic school, its application has not been illustrated in churches of that type, which are seldom true in design and seldom seem to be true to our own period. Wren, on the other hand, does not sham; and his style in general is in accordance with the feeling of our times, which is for an architecture of expression rather than for one of construction. In other words to follow in the school of Wren (not, that is to say, to imitate in detail) is to design churches in the same style in which we design our other monumental buildings and even our important houses, and that is at the bottom of the attraction one feels for his churches. If the mediaevalist in religion points on the other side to the unchanged character of the Church of England, it is not necessary to enter into that controversy; for the Church of Rome, as to the unchanging character of which there is no controversy, has distinctly abandoned the mediæval style of building without apparently bestowing a thought upon the matter. At any rate one charm that Wren's churches have for the writer of this article is that they are of his own time, and after their adaptation to modern usage in the Church of England, are so nearly of out's that they are both satisfactory in themselves and suggest the possibility of building churches that will not make us feel, when we enter their doors, that we have entered upon another century and a dead one.



To say that Wren did not sham may require the support of illustration. One is given in Fig. 1. If the drawing had been labelled "ceiling" instead of "roof," it would give no handle for doubt. It is in reality a ceiling, an obvious plaster ceiling, made in barrel form and lightened (greatly to the advantage of its beauty) by penetrations for attic windows. The columns are of stone and the beams on them, which carry nothing but a wooden roof and wooden windows, are of wood. This is not only a reasonable construction but looks so. Sir Gilbert Scott in his great London church, St. Mary Abbotts at Kensington, has also a barrel shaped ceiling. It is of wood, but, if we concede that this is a more honorable material, we must stop there; it is not penetrated and is very dull; it springs from a cornice which is some distance above pointed windows, which look foolish in consequence.

If we approach the study of Wren's plans with an open mind, they are full of suggestion, being indeed full of variety. Wren's method appears to have been to include within the walls of a church all or nearly all of its available building area. As the lots were of all shapes the resulting form was often extremely irregular. To reduce these to practicable form there were three principal agencies—tower, vestibule and aisle. By the varied disposition of these Wren produced a series of plans extraordinarily varied, but for the most consisting in the main of a square or oblong area not recessed at the east end. This suited the manner of conducting the church services that remained through the Restoration period and beyond, as a legacy from the Presbyterianism of the Commonwealth. The "three-decker" pulpit rose from among the pews, with seats for the three performers of the service:—the minister who read the service in the middle; below him the clerk who led the responses of the congregation; and above, high up so as to rake the galleries, the preacher abided his time in a black gown and bands. These functionaries remained immovable throughout the service; there was no separate gangway needed for their movements, to keep them apart from the congregation. They did not enter the communion railing except upon the infrequent occasions when the sacrament was administered; and its administration was done with studied simplicity. There was therefore no attempt at what is now-a-days called "an east end". Wren always dignified his communion table with a handsome oak reredos; but the space occupied by the railing was small; it was on the floor level and surrounded by pews, making thus rather an incident in the east end than a motive in its plan. The church was regarded as a chamber in which the central point was the pulpit. The sacraments had a space reserved for them at opposite ends of the church; the font near the entrance, the communion table at the other end. The ceiling followed the floor plan and consists usually of a cornice returning along the east and west walls and a central panel or a series of panels symmetrically arranged over the whole church. This is the first thing that meets the eye now, as one enters the church, and the first impression is usually of a chamber rather than of a church. It is extraordinary how subsequent perception of the floor arrangement dissipates this first idea and how impossible it is to return to it in spite of the ceiling. It would be perhaps well to give an example here of one of the churches, plainest in plan, and reserve for a future occasion an illustration more full of attractive suggestions.

Fig. 2 is a plan of St. Nicholas Cole Abbey taken from an old plan. The pulpit as drawn is all that was shown on the plan, but the seats no doubt, as in other examples which remain unchanged, ran to the east

wall, leaving a space round the communion rail about equivalent to that between the railing and the foot of the pulpit steps.

The south side used to be blocked by a building so that there are windows only on two sides. The difference in the walls is an advantage. The order is quasi-

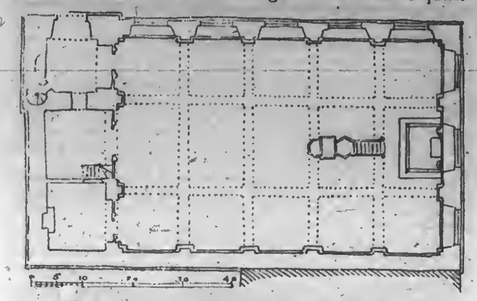


FIG. 2.—PLAN OF ST. NICHOLAS COLE ABBEY.

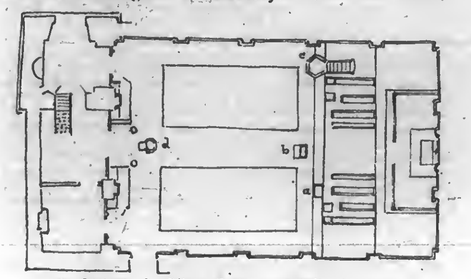
Corinthian; Wren was apt to use an interesting freedom in the employment of "the Renaissance box of bricks.' The moulding of the ceiling beams is that of the cornice down to the bottom of the corona, and the beams, which have a soffit the width of the upper diameter of the pilasters, mitre with this much of the cornice. The result is neat but a little flat; it suggests coffered panels. The walls frieze and soffit of ceiling and beams are coloured yellow; the order (including the beam mouldings) and the dado black, touched with gilding; an effect striking but satisfactory.



a.—Lectern. b.—Litany Desk. c.—Pulpit. d.—Font.

FIG. 3—SEATING PLAN FOR ST. NICHOLAS COLE ABBEY.

In Fig. 3 is shown a modern seat arrangement compounded of St. Nicholas and other churches; that is to say, there is in St. Nicholas an eccentric massing of the choir on one side, and it seems better for the sake of a descriptive plan, to adopt the arrangement usually to be found in other churches. The dignity is apparent, obtained at the expense of a good deal of space, but it is the nature of the plain plan to get its effects by space; and indeed the lesson to be learned from this adaptation of Wren's plain plans is the excellence of the effect thus obtained. The reduced seating accommodation in a city church is never sufficiently reduced to meet the sparsity of the congregation; for further accommodation, in a church with greater need for seats, the body of the church would stand elongation. If this were done and the ceiling not returned but made to run only from west to east, reflecting in some way the subdivisions of the floor, there would be a good modern church.*

W. A. LANGTON.

*The organ in St. Nicholas Cole Abbey, as in most of Wren's churches, remains in a gallery at the west end.

BUILDING MATERIALS AFFECTED BY THE NEW TARIFF.

Among the changes in the Canadian tariff announced by the Dominion government are some which affect certain lines of building supplies. The duty on plate glass not bevelled in sheets or panes not exceeding seven square feet each, n.e.s., is lowered to 10 per cent. ad valorem. On the same material in sheets or panes exceeding seven square feet and not exceeding 25 square feet each the duty will be 25 per cent. ad valorem.

The maximum duty under the British preference on china and porcelain ware is reduced from 20 to 15 per cent. ad valorem; that on common and colorless window glass from 13 1-3 per cent. to 7½ per cent.

*From a Paper by Walter Jones M. I. Mech. E., read before the Institution of Heating and Ventilating Engineers of Great Britain.

NORTHWEST NOTES

Branch office of the CANADIAN ARCHITECT AND BUILDER,
310 McIntyre Block, WINNIPEG, June 14, 1904.

At the last monthly meeting of the Winnipeg Builders' Exchange it was unanimously resolved that the Exchange adopt the Uniform Contract and that members of the Exchange shall sign no other, the uniform general conditions of which are as follows :—

The Contractor will set out all the works in accordance with the specifications and drawings and have all necessary levelling carefully done and assist at any time or times that may be desired in testing any of the said works.

The Contractor is to employ a competent foreman for each different branch of the trade.

No portion of the work is to be sub-let unless by written consent of the Architect.

The Contractor is to furnish all transportation, apparatus, scaffolding and utensils needed for performing the work.

The drawings, figures and details are to be considered part of and as illustrating the specifications and must be carefully followed. The details are intended to be final concerning all sizes, lines, etc., therein set forth and are not to be deviated from without the written direction of the Architect. Figuring and notes are to be more authoritative than scale sizes, not only in the details but in all drawings, otherwise sizes are to be scaled as accurately as possible and followed.

If the plan and specifications contradict one another or are ambiguous the attention of the Architect shall be drawn to the fact and his decision obtained before the work is undertaken.

The Contractor is to be responsible for all violations of the law caused by obstructing streets and sidewalks ; to obtain correct lines (except side lines) and grades from the City Engineer ; to comply with all requirements of the building by-laws of the City ; to take out and pay for all necessary permits for all temporary obstructions and enclosures, and to pay all proper and legal fees to public officials ; to be responsible for all damages to neighboring proprietors caused by the construction and carrying out of the work in a negligent or improper manner and to hold the proprietor harmless from all claims in respect thereof, and at the completion of the work shall remove all rubbish and waste material from the building, grounds and street and leave the same clean and relay all sidewalks that may have been removed or damaged through the progress of the work to the satisfaction of the Architect.

If at any time the Architect considers any workman incompetent, the Contractor will be required to dismiss the same if requested by the Architect so to do.

Should the work run on until the cold weather, Contractor must heat the building at his own expense if necessary for the completion of the work to be done by him and to the satisfaction of the Architect.

All drawings and specifications are and shall remain the property of the Architect.

The visitor to Winnipeg cannot fail to be struck immediately with the air of prosperity with which he is confronted; on all sides he is face to face with a spirit of progress and confidence, which speaks well for its future and carries the conviction of an established prosperity, and stands in somewhat striking contrast with the deliberate steady ways of the eastern provinces. Undoubtedly Winnipeg has secured for itself not only the premier place among western cities, but fixed itself as the great Commercial City of Western Canada.

The advancement of Canada's Prairie City is clearly marked by the aspect which meets the observer on his journey through the principal streets. Side by side with the fine modern structures which are rapidly springing up on all sides, are still to be seen many of the original one and two story buildings looking strangely antique in contrast to the present-day sky-scraper which is fast gaining popularity.

Perhaps one of the surest marks of success is to be seen in the continual flow of commercial men passing through the city.

The great scarcity of hotel accommodation is another indication of the city's rapid progress. There are altogether some fifty hotels in the City, all catering for the commercial community. Until recently this was considered ample for the city's needs; now, however, hotels are finding increased difficulty in meeting the demands made upon them, and are finding it necessaay to make preparation to supplement their present accommodation.

A large block known as the Assiniboine Block, and at present used as an apartment block, has just been purchased by Messrs. McLean Bros., and is to be converted into an up-to-date hotel. The building is situated in the Main Street, and when completed is expected to be one of the finest hotel structures of its kind.

O'Connor's Hotel on Main St. is also to be replaced by an imposing new building, designed by Mr. J. Cadham, which will be fitted up with the latest improvements.

The permit for the C. P. R. Hotel and new station has been granted. Work is expected to start at once. All the details of this hotel are arranged with the greatest precision, and whilst the outward design is perhaps somewhat plain and uninteresting, it is skilfully planned in point of utility and equipment.

The Queens Hotel on Portage Ave. is to be remodelled under the direction of Mr. Sam Hooper. The plans, which have been submitted, show a well arranged building.

The Leland Hotel, which stands on one site of the City Hall Square, is also to be remodelled. A new billiard room is to be furnished, a new bar and saloon, and additional stories added, which will bring up the capacity to one hundred and thirty bed rooms. The work is under the direction of Mr. F. R. Evans. This hotel stands adjoining the new Union Bank Building now under construction.

The St. Nicholas Hotel is also being remodelled, and an annex is to be added. This work is also under the direction of Mr. F. R. Evans.

The Windsor Hotel is in process of complete renovation. Under Mr. Evans' supervision a new front is to be installed and additions which will greatly enlarge its capacity. The National Hotel is also to be altered and enlarged from plans by the same architect.

An imposing block of business warehouses in the occupation of Messrs. Tees and Persee, Limited, has just been sold to be converted into a hotel, and work is expected to commence at once. The block is prominently situated on Market Square.

A scheme has just come to the front in which the proposal is to erect a mammoth hotel on Main St. to have some 250 bed rooms, and equipped in the most approved style. The promoters are prominent local men.

It will, of course, be some time yet before all this work is completed, and, at the present rate of progress, it is not at all unlikely that the additions will scarcely meet the natural increase of business.

The building permits issued up to a recent date, and which cover in the main, either business premises or dwellings, give a total of some 1,100 buildings, at an aggregate cost of nearly $5,000,000, and it is not expected that this will materially relieve the situation. To this amount should be added the cost of the C.P.R. Hotel and station, the amount of which has not yet been published, but which is considered to be in the neighbourhood of one and half millions.

The City Hall, which occupies a fine position in the centre of the city, is attractive in appearance, is not scarcely commodious enough, although, at its erection a few years since, it was thought to have been sufficient to provide for all expected development. The insufficiency of accomodation in this building will, however, be met in a measure when the new Library is completed by the removal to that building of the present library, reading room, etc., thus giving additional space for offices.

There are quite a few fine business blocks in course of erection, prominent among which is one for Messrs. Miller, Morse & Co. on McDermott & Adelaide Streets, forming a block some 260 x 98 ft. It is to be 5 stories high, and will be of mill construction. It is worth noting that this is the first building in Winnipeg built on this principle. A prominent feature is to be the main doorway. It is to be arched, finished in carved stone, with oak door with grill work in upper panels. The lower stories of building will be constructed of rock face natural stone, the upper part in stone and white brick. The architect under whose direction the work is being executed is Mr. J. Cadham.

There are many conditions with which the builder in this district has to contend which are not met with elsewhere. One of these has been very apparent recently owing, in part, to the recent heavy fall of rain. On one of the main thoroughfares some excavations had been made ready for the foundations of a large block, but owing to some delay were not immediately proceeded with ; in the meantime the heavy rain had come, with the result that although the perpendicular sides were considered to be sufficiently shored, the whole of the sidewalk for some distance fell in, the soil below having shrunk owing to its peculiar nature, the heavy weight of the cement sidewalk bulged out the under soil until the timber supports below were forced out. This occurrence is attributed to the peculiar nature of the soil, which carries some distance below the surface a layer of "shale," very much of the nature of quick sand, and which, when disturbed, is a great source of danger. Builders often find it necessary to provide against this peculiarity by supporting the end wall of a range of buildings during erection until the building is well pinned together and sufficiently strong to carry its own weight.

At another point in the city a similar situation exists, but of a more serious nature, involving danger to a neighboring building. In this instance the Contractor had made his excavations ready for his foundations right up to the adjoining property. During the night the whole of the wall adjoining, and which to all appearance is a most substantial one, sank bodily several inches, without previous warning or showing any sign of cracking (except at the point of parting.) The cause of this particular accident has yet to be decided, but it will, in all probability, be traced to the above mentioned cause. The subsidence caused quite a panic at the time and the building inspector, Mr. Rogers, was hastily summoned. He at once set to work to protect the building, which was done by strapping through and through at top and jacking up the wall above the foundations. By this means the building has been raised to almost its former position.

The Winnipeg Builders' Exchange held their monthly meeting on June 7th in the offices of the Association. There was a good attendance of members, and much discussion on important matters. It was reported by the Committee that the Architects had been interviewed and were almost unanimous in acceeding to the request to deposit a copy of plans and specifications of prospective contracts at the office of the Exchange from time to time. The Architects had also approved of the "Uniform Contract" which had been submitted to them. It was also resolved to draft a uniform form of tender for use by the members, and have same submitted to the next meeting. During the meeting the secretary, Mr. W. W. Daly, addressed the members on the subject of the "Aims and Purposes of the Exchange." The address was received with great enthusiasm and a vote of thanks passed to the secretary. It is proposed to have the address printed.

WAREHOUSE CONSTRUCTION.

If a furniture storage house, a prominent situation on an important street and if possible, where the passing thousands see it, is of great advantage. This need not be in an expensive neighborhood or a retail block and may even be surrounded by cheap stores or residences. But if it is a noticeable building and has substantial signs and is on a car line, or where it is sure to be seen by a great many of your city's inhabitants, you will get ten times as many personal and telephone calls for rates and information as if on a back street, and can save considerable in advertising. It is well, also, if it can be on a business street in the edge of the business district, so that a good portion of the ground floor front can be used as a sales room for second hand and new furniture, or rented out as stores to tenants. But in this connection it is essential to consider whether the patronage of the great middle and poorer classes is expected, or mainly that of the well-to-do and "tony" set, because the latter are repelled and very reluctant to trust their goods under such circumstances, and willingly pay higher rates where the building is held strictly for storage purposes, especially if it says "fire proof," and has formidable iron gates and its front is built with castillated walls and other evidences of physical and financial solidity.

If a heavy merchandise or "dry" storage house, it is not important that it be in a prominent location, or even have a street facing, but it is, of course, desirable that it have a good railroad side track and easy delivery platforms to customer's teams, and the nearer it is to the centre of the wholesale district, the better. If the city is on navigable water, it ought to have both dock and railroad platforms—but it is probably more desirable that the building be within reasonably easy reach of the wholesale customers and freight shipping depots than that it have either of these very desirable conveniences, because goods usually go out in smaller quantities than they come in and by expensive horse and truck, so that a saving of time when goods are wanted, and, a long haul, is an economy to your customers which they will appreciate. This does not apply to an exclusive transfer and forwarding business where the warehouse can be located at the transfer yards in the outskirts of town so long as ample shipping facilities and equal freight rates are had. I venture to suggest if it will not be better, if on railway trackage, that it be on some large railway system not already well supplied with storage warehouses in your city, especially if such a line has equal facilities and advantages on in and out freight—because of the help you will naturally secure from the railroad directing their enquiring customers to you.

It is also wise, before announcing a settlement upon a location, to consult the officials of, say the railway company on whose line you intend building, learning what obstacles, if any, there may be in the way of good switching service to the location—and you can also sometimes secure a specially advantageous switching rate from them, which they would not make you later after you had started to build. You are also more apt to learn from them than from any other source what rearranging or large changes in tracks or railroad facilities which may effect you, are planned for the distant future.

The same general observations apply as to the locating of a cold storage warehouse. Where a considerable share of its merchandise will come from and go to the local wholesale produce commission merchants by team, it is obvious that to be within convenient reach of them is most desirable.

It would seem preferable, in all cities except of the largest class, that a storage plant embrace several lines of warehousing, as say, dry merchandise, U.S. bonded and cold storage, and I would also favor including household goods, for to some extent the advertising of one will help the other, and it is certain it will involve but a small increase in crew to perform the labor in several branches, under competent management. But these branches of storage should not be conducted in the same building, unless it be the dry storage and U.S. bonded, and then it is essential to comply with the government regulations requiring an independent street frontage with separate doors and a tight partition with locked doors separating the bonded from the free storage space.

For a practical and economical plant, I suggest an ideal arrangement would be two non-fire-proof sections, divided by a fire-proof section, and I would, in view of the only slight additional cost, even carry it as far as to make fire-proof the unloading platforms opposite the fire-proof section, and any other communicating parts. If cold storage in connection with heavy merchandise storage is to be conducted, and if it is desired to store fish, oranges, lemons and other maladorous or penetrating commodities, as well as sensitive butter and eggs, it would be well to place the merchandise section between two separate and (except for the refrigerating piping, etc.,) entirely independent cold houses. This will involve some additional cost of insulation but will avoid chance of damage by communication of the odors, and of course the division of the risks by heavy fire walls will always work to your advantage in fire insurance rate.

In a climate where a fairly cheap ice supply can be secured in mid-winter, it would seem highly economical to build your cold storage house with continuous, indirect circulation air chamber between the main insulation and the wall, through which to circulate the air from a stored body of ice, as is in successful operation now in several houses. This is found to secure at the very small expense of a fan power and without labor or handling of the ice, a temperature of about 40 degrees near the outside of the insulation, so the ammonia or ice-salt-and-chloride-of-calcium or anhidrous dioxid, or whatever system is used for the sharper refrigerating, will only have to reduce from a uniform temperature of about 40 degrees F.

There may be another important good served by this indirect circulation in the outer space of the insulation in that it would catch up any leaks of warm air from outside and carry them along back to the ice body, but in fact under reasonably still weather conditions there would probably be, if anything, a slight surplus pressure in this circulating air chamber, so that any openings through the wall would simply serve as slight out-leaks of the inexpensive ice chamber air.

In connection with an ideal arrangement, it would seem an advantage if the railway track can be at an elevation, and come at the back of the buildings on a level with the second or third floor of our, say six-story building. This would save something in elevator

service, would reduce annoyance from stragglers and danger of theft, and allow team platform and delivery access under track at the lower floor level somewhat protected from the weather.

It is unquestionably good practice where the warehouse is not large enough to require a separate delivery and receiving foreman, to have these two departments close together.

Among several reasons why it is wise to have floor strength uniform on each floor of a warehouse, is the fact that the city building inspector always accredits a floor with only the strength per square foot of its weakest part after dividing by their usually high factor of safety.

It is regarded wise to have all floors slightly inclined towards the elevator shaft so that in case of a flood of water from fire engine, or an unroofing storm, it will drain off promptly. This incline need not be enough to be noticeable in handling goods. Sometimes the ground level floor is perceptibly inclined from the rear railway track end to the front truck delivery end, to aid the movements of trucks in the easy transfer of goods directly through the house.

The number, kind and general disposition of the windows in a storage warehouse have generally not received full attention in even the newer buildings erected for this purpose. Very few windows and those placed where they can throw their light down the aisle, and high so there will be the least obstruction possible, would certainly seem good judgment. Every window exposure is a serious outside fire-hazard from an insurance standpoint, bleaches the goods which happen to be opposite it, besides heating the house in summer and cooling it in winter, and presents a vulnerable spot for storm damage and for burglars. While some daylight for handling goods is needed and is much better than to rely on lanterns, and some airing may occasionally be necessary, and direct outside access to each floor and section is demanded by the fire department—it is possible by one window at each end of each main aisle to secure all these with comparatively small openings.

If the glass is the ordinary ¼-inch wire-glass, the danger of fire from without is less and if the wire-glass is set in iron or all sheet metal shod sashes, frame and casing, the danger from outside is reduced to a minimum, and you secure the main protection of an iron fire shutter without its disadvantages. Much help in diffusing light is obtained by having the brick walls at window openings tapered off at 45 degrees on sides and top both inside and out, so that the light can reach each side as well as straight in front of the window. Luxfer Prism glass in aisle windows is as fire resisting as wire glass, and will secure fair light for a great depth through a room, and will prove a desirable feature.

Probably the best arrangement of floors for a non-fireproof building for general merchandise storage, is what has been called the highest type of mill construction, in which only postline girders are used, the floor planking reaching in a continuous line from girder to girder and by virtue of its own stiffness holding the load. The floor planks are somewhat thicker, usually four to six inches, are tongue-and-groove matched together and are of double length reaching over two sections of floor so as to avail of the cantilever effect of the bending tendency.

The writer has devised a system of trussing by inexpensive sheet metal the entire under side of such floors, which has been highly approved by some authorities and which is designed to increase the floor stiffness sufficiently to avoid the need of extra thickness, while it also adds to the slow burning quality of the building.

The number and location of the power elevators is a subject upon which there is divergence of opinion, and many of the best architects and builders strongly advocate grouping the elevators at least two in a stack, but there seems to the writer to be formidable reasons why it would be better policy to scatter them. It is recognized from insurance reasons nowadays almost essential to enclose the elevator shaft in brick, and where the same general class of storage is conducted on both sides of a party wall there is probably no reason why the elevator stack cannot be set in the wall, half in each side, thus serving both sections. We have recently constructed a very satisfactory dry storage house in the writer's city in which, at his suggestion, the elevator was located in the aisle at the back or railway track end. This allows of directly trucking on of goods from the cars for upper or lower stories and is found to save almost a carload of the valuable room on each of the floors except the track level floor. On the latter, of course, a separate side door has to be provided for passing through goods intended for storage or handling on that floor.

The wood now largely preferred for its strength and evenness of grain is Washington fir, which can be had for posts in almost any size timbers. It has within a few years been determined that a large augur hole bored through the centre length of each post and heavy timber will result in the seasoning cracks running to the center, leaving the outside solid, and of course, adding to the sightliness and strength of the structure.

It is often dangerous to cover with oil paint stringers and other construction timbers, because of the tendency to dry-rot when the surface is thus sealed, and it has been a common experience in some parts of the country for the building inspector to make the starling discovery that some main supporting stringers so painted consisted of an inch shell with the entire centre of dry punk. This condition never results, even where timbers were somewhat green when erected, if they are left unpainted, but where a more finished appearance is desired, a coating of any of the several cold-water fireproof paints or of white-wash, will form a good surface, and at the same time add in a probably valuable degree to the slow burning qualities of your building. In this connection it is worth mentioning that these coatings are now easily applied by any large painter, with the use of a spray machine and at an expense for labor of less than one-third what it would be if done in the old way by hand and brush.

As an additional fire protection, it is wise to provide sand-fire doors covered with tinned iron and closing automatically in case of fire by a fusible plug and retaining cord at all wall and elevator openings.

Eighteen sculptors in Europe and America are said to have expressed their intention to compete for the designing of the proposed memorial shaft of the South African Memorial Association.

The Board of the United States General Appraisers are said to have just ruled, in effect, that architects are "artists," and that architectural drawings, for tariff purposes, are dutiable in the same class with "paintings in oil and water colors, pastelz, pen and ink drawings and statuary, not specially provided for."

THE MEANING OF ART.

The word "art," and its adjective, "artistic," are greatly misused, says a writer in Building News. The ordinary Englishman regards art as some sort of accomplishment or process of decoration by which an object, no matter what it is, can be made pleasing or artistic; he thinks it can be applied like a coat of paint or a wallpaper, to any portion of a building or piece of furniture, or anything else, after it is constructed or made, and that the man who can do this is one who can draw pleasing or pretty designs, and can apply his "art" to anything from a fire-grate or coal-scuttle to the decoration of a room. Such is the view of the modern Philistine in art matters. The true meaning of art or architecture is construction dominated by an idea of order or purpose, and the man who designs a building or a fitting or piece of furniture for a given purpose is the real artist. He must commence to exercise his art at the very beginning—to shape his stone, wood or iron according to the use it has to fulfil, not to leave it for others to give it an extraneous expression, or by adding to it a few ornaments. If art, as Morriss says, is "man's expression of joy in his labor," craftsmanship must be actuated by it. Art and craftsmanship must stand or fall together, and it should be our aim to bring them once more together.

INVENTOR OF PORTLAND CEMENT.

Very few of the thousands who make use of Portland cement, and still fewer of the millions who benefit by its use, have ever head of Joseph Aspdin, the inventor of a material to which we owe many of the great engineering works of the present day. Aspdin was a Leeds brickmaker who, in 1813, conceived the idea of combining chalk with clay from the river bed, drying and calcining the mixture at a high temperature. In 1824 he patented the invention, and soon afterwards opened a small cement manufactory at Wakefield, and a few years later his son, William Aspdin, established a cement factory near Chatham. The peculiar advantages of the new material were soon recognized by engineers, and Brunel, as the Builder points out, was one of the first to make use of it, employing Aspdin's patent cement in the construction of the Thames Tunnel. It is true that rival claimants have arisen to claim the honor of inventing Portland cement, but it is now recognized by competent authorities, not only in England, but also in France, Germany and Italy, that the palm belongs by right to Joseph Aspdin. The suggestion is now made that a public memorial should be rised in Leeds to the inventor of Portland cement. The movement should meet with support in America, where the Portland cement industry has shown more rapid progress and has reached greater proportions than anywhere else in the world.

The Royal Institute of British Architects have protested against the new drainage by-laws introduced by the London County Council which require, in duplicate, complete plans, sections and elevations of every floor of a building to be submitted not only in the case of new systems of drainage but any alteration of an existing system.

Mr. G. Gilbert Scott recently read a paper on his design for Liverpool Cathedral before the Liverpool Architectural Society, in the course of which he said he had dreams of quite another style; but his ideas had not had time to mature. Gothic could not go much further: it was nearly at the end of its tether, and before long would die out as completely as it did in the sixteenth century.

BY THE WAY.

A house in Nevada is said to have been constructed entirely of beer bottles and cement. I can easily conceive of many houses that might have been built but for the abundance of beer bottles.

× × ×

According to tests recently made at Kew and Chelsea by Prof. Oliver, the atmosphere of London after a dense fog contains a deposit of acids and carbon exceeding 6 tons to the square mile.

× × ×

Prof. Goldwin Smith asserts that the house in which he resides, known as "The Grange," was built in the year 1817 at a cost of only $4,000. The house is commodious in size and substantially built, in the Englisb manor-house style. The interior is finished in oak and walnut, this material being used in abundance for wall panelling, etc. His old house serves as a concrete illustration of the tremendous advance which has taken place in the cost of building in Toronto during the last seventy-five years.

× × ×

The expected contradiction has come to the announcement so widely published in the architectural papers of the alleged discovery that by the use of 2 per cent. of tannin in the moist clay the ancients made bricks which were 350 per cent. stronger than those made by our modern methods. In recent tests by Sege briquettes composed of 2 parts sand and 1 part raw clay broke when fresh at 0.56 kilogrammes per sq. centimetre, and after having been stored for three weeks, at 0.92; briquettes containing tannin broke at 1.01, those containing starch at 0.75 and those containing dextrin at 1.71 kilogrammes per sq. cm.

Dr. Warner, of London, is given as authority for the statement that small heads and physical deterioration are caused by living in high buildings. This conclusion is said to have been reached after an examination of 100,000 children. Unfortunately Dr. Warner has no intelligent reasons to advance why people's heads should grow smaller the farther skyward they go. Presumptuous as it may seem, I am disposed to doubt the accuracy of Dr. Warner's, theory, so far, at least, as this side of the water is concerned. I have known persons whose heads not only did not grow smaller but actually got "swelled" as the result of living and doing business in a modern sky-scraper.

× × ×

At St. Augustine's Church, Elkridge Landing, a suburb of Baltimore, a mortar-eating bug is reported to have been discovered by the parish priest, Rev. Francis P. Doory. The priest noticed that the brickwork and marble facing, back of the altar, were falling to pieces and that the entire altar seemed to be in danger of collapse. He promply called in some workmen, who discovered that the cement binding the marble to the brick had been eaten away. With the removal of the first slab a multitude of cobite bugs were disclosed, hundreds of which were captured. Placed in a pail with several pounds of the dried mortar the bugs proceeded to devour what appeared to be their natural food, thus definitely establishing their destructive powers. These bugs are said to be a new thing to the naturalist, and scientific investigation will be awaited with interest.

THE ARCHITECT BEFORE THE LAW.*

II.

By S. G. Archibald, Advocate.

Mr. President and Gentlemen:—

To-night I propose dealing with the questions of servitudes in general, and more especially of mitoyen walls, and with the question of risk, i.e., at whose risk is the building before acceptance by the proprietor? Upon whom does the loss fall if the building be destroyed by force majeure before delivery? Are the architect and builder deprived of their right to recover the value of the work already done?

The question of servitudes is perhaps not one which will appear so immediately practical nor interesting as that of the 10 year guarantee; at the same time it is one with which architects ought to have a good general acquaintance. As a matter of fact, I presume that in the daily practice of your profession you have acquired a sufficiently practical knowledge of the question. I propose to put into systematic form the general ideas upon the subject which form the basis of our law, and to cite cases from our jurisprudence, which have given practical application to these theories.

In the first place, what is a servtiude? A real servitude is a charge imposed upon one property for the benefit of another belonging to a different proprietor. From one point of view then a servitude implies a right, from another a charge. The property burdened with the servitude is called the serviant tenement; that which enjoys the right is called the dominant tenement.

While a servitude resembles an obligation in almost every particular, it differs from it in this respect, that it has to do with properties and not with individuals. The right and the charge pass with the properties. The individual may be discharged from an obligation upon the payment of a certain sum of money, but the proprietor of the serviant tenement cannot liberate himself from the servitude by offering to pay its value in money. It is in realty a sort of dismemberment of property so far as the serviant tenement is concerned, and, so far as the dominant tenement is concerned it is a sort of quality in the property which forms part of it, and which the owner cannot be obliged to sell. Thus, for example, if there is a right of way in favour of my property across my neighbour's field, he cannot force me to forego my right by offering to indemnify me. If, however, my right of way has becnme, owing to cumstances, particularly burdensome, he can offer me another right of way over a different part of his property, and I will be obliged to accept it if the proposition is reasonable, and this will be a matter for the courts to decide.

It, of course, goes without saying, that the proprietor of the dominant tenement may sell or otherwise give up the servitude which exists in favor of his property, and, in such case, neither property will be affected with the servitude for the future.

No servitude can be acquired except by title, as the French maxim has it, "nulle servitude sans titre." It is not possible, therefore, to prescribe a right of way even by making use of i for 30 years. There must be some definite title establishing the right invoked.

There are 3 classes of servitudes: (1). Those derived from the natural situation of the properties called natural servitudes. Such, for example, as the obligation of a lower land to receive the natural fall of water from land above it.

(2). Servitudes established by the law, or legal servitudes. Such, for example, as the obligation to contribute to the erection of a mitoyen wall.

(3). Servitudes established by the act of man.

The distinction between the first two is only a distinction of words, because both classes are servitudes sanctioned by the law, and which exist independently of the will of the individual proprietor. Servitudes are really, therefore, those imposed by law and those which the individual chooses to place upon his property, and, as a matter of fact, these latter are the only ones which can strictly be called **servitudes**, because they are the only ones which really derogate from the state of **legal** liberty in which all property is a servitude, being a modification of property can only fairly be applied to those modifications made n respect of a particular property by the act of man. Our code, nowever, makes the division of servitudes into the classes just mentioned, and we must adhere to that division.

Under the head of natural servitudes the code treats of the obligation to receive waters from a higher level, of boundaries, and of fences. While we have no time to take up these questions in detail, it may be remarked "en passant" that the proprietor of the higher land has no right to aggravate the servitude in any way. Thus, for example, the Privy Council in the case of Frechette v La Compagnie Manufacturer de St. Hyacinthe (9 App. Cas. 170) decided that the proprietor of land occupying a higher level who had constructed works whose effect was to accumulate the water and to deepen the channel by which the water passed to the neighbouring land, had aggravated the servitude. Numerous other cases might also be cited forbidding any such aggravation. With respect to "bomage," this may be demanded at any time, and the right to make such demand is imprescribable. The cost of making a bomage is borne equally by the parties, with the exception that the cost of measuring is borne proportionately. Needless to remark, if legal contestation arise in fixing the boundary, the costs are borne by the losing party.

While the right to demand a bomage is imprescribable, it cannot be exercised arbitrarily, and the law in Art. 941 C. C. P. lays dowo the only cases in which it may be demanded. Where a legal bomage has been demanded, the surveyor makes his report, and the Court then, by its judgment, establishes what the line between the properties shall be. The parties have a right to be heard upon the surveyor's report, and no judgment, fixing boundaries, without a surveyor's report, and, upon which the parties have had a chance to be heard, is sound. Such is the jurisprudence of our courts.

First and most important among the legal servitudes is the obligation to contribute to the erection of mitoyen walls. In general we mean by mitoyenneté the co-ownership in indivision of an intermediate object serving as a boundary and as a separation between two contiguous properties, and especially a mitoyen wall is one which belongs in common undivided ownership to two owners whose properties it separates. Each owner has thus an equal and joint right in every part of the wall.

Mitoyenneté constitutes a community of property quite different in many respects from the ordinary community of property. It differs as to proof of it, as to its duration, as to its effects, and as to the manner of its acquisition.

As to proof, Arts 510, 511, C.C. give us a system specially adapted to it. They are as follows: (510) "Both in town and country, walls serving for separation between buildings up to the required heights, or between yards and gardens, and also between enclosed fields, are presumed to be common, if there be no title, mark, or other legal proof to the contrary." (511). "It a mark that a wall is not common when its summit is straight and plumb with the facing on one side, and on the other exhibits an inclined plane; and also when one side only has a coping, or mouldings, or corbels of stone, placed there in building the wall. In such cases the wall is deemed to belong exclusively to the proprietor on whose side are the eaves or the corbels and mouldings.

As to its duration. The ordinary rule regarding property is that no one can be compelled to remain in a state of undivided ownership. He can always put an end to the indivision by demanding a partition. In the case of a mitoyen wall neither party can demand a partition unless his neighbor consent. There is, then, only one means of ceasing to be undivided owner and that is the abandonment of the common wall.

Ordinarily, when two persons are owners in common of a certain thing neither party can make any change in it without the consent of the other. Not so, however, with respect to the mitoyen wall. Each party can can use it in such a way as to benefit himself, on condition only that he does not injure his neighbor in any particular. Thus, for example, he may build against the wall, he may place beams in it to within 4 inches of its thickness, and he may raise it, if such a proceeding is useful to him.

As to its acquisition. As a general rule no one can be compelled to sell his property save for purposes of public utility. This rule, however, suffers exception in the case of a wall separating two contiguous properties. He who has not contributed to its erection may acquire the common ownership of it by paying an indemnity composed of (1) half of the value of the land on which the wall is built, and half of the actual value of the wall or part of the wall of which the mitoyenneté is acquired. It is to be remarked that this right only exists in favor of the proprietor of the land immediately joining the wall, so that if A has left ever so small a strip of land between his wall and B's

* A series of lectures prepared for and delivered before the Province of Quebec Association of Architects, 1903, and published by permission.

property, B cannot acquire the mitoyenneté of the wall. This at least, is the opinion of the great majority of the French authors and of the Cour de Cassation in France, although there is a good deal to be said in favor of the contrary view. De minimis non curat lex—and if the strip be very small it might fairly be agreed that it should not be taken into consideration at all.

It goes without saying that the mitoyenneté in the wall must first be acquired before the neighbor acquiring it makes any construction upon it. Thus in a case of Joyce vs. Hart, decided in the Supreme Court (I. S. C. R. P. 371), the builder was condemned to demolish his construction built on a wall of which the mitoyenneté had not first been acquired. And in a case of Bruchesi vs. Desjardins (R.J.O. 2 C.S. page 436), it was decided that a neighbor can only acquire the mitoyenneté of a wall by conforming to Art. 518 C. C. which says, "Every owner of property adjoining a wall has the privilege of making it common in whole or in part by paying to the proprietor of the wall half the value of the part he wishes to render common, and half the value of the ground on which such wall is built," and when the wall in question is not straight and not proper to serve as a mitoyen wall the neighbor cannot without the consent of the owner or legal procedure take possession of the wall and demolish it, with a view to its construction as a mitoyen wall.

The question is sometimes asked as to whether or not a party who is building a wall which is not mitoyen can force his neighbor to allow him to take 9 inches of ground on his side of the line. There is no doubt that he can, but of course the neighbor will then have the right to acquire mitoyenneté in the wall on paying half of its actual value, and will have nothing to pay for land. It would always be prudent to notify the neighbor that you were taking advantage of your right to the 9 inches in order that he might oversee the work, if he so desired. A very interesting point has been raised as to whether one neighbor can take more than 9 inches of the other's ground when such is necessary for a footing course. The Court of Appeals in Keough and Lolin and in Rafter vs. Burland have seemed to deny that right. The Superior Court, however, in the last case upon the subject (Roy vs. Strubbe) has held that he could. This case has gone to appeal and is not yet decided. The reasoning employed in favor of the proposition seems to be irrefutable, but the points must still be considered as unsettled until the Court of Appeals shall have passed upon the last case referred to.

Walls separating two buildings, or two yards, or two gardens or a yard and a garden are presumed to be mitoyen and our courts have held (McKenzie vs. Tétu 12 L.C.R. 257) that mitoyenneté is a legal presumption which throws the burden of proof upon the person objecting to it, and the objection can only be maintained by a title or by certain marks or by legal proof. Article 511 C.C. already cited, indicates what these marks are. Of course these marks must have been placed in the wall at time of its construction or if placed later the consent of the neighbor must be proved.

Legal proof of the non-mitoyenneté may always be made, the only question that then arises is, what is legal proof? Apart from documentary proof our law allows verbal evidence to be made in certain specified cases only, and oral testimony will not be admitted to show the consent of a neighbor to the erection or placing of a mitoyen wall (Leduc vs. McShane, 29, L.C.J., p. 56). Nor will it be admitted to show the necessity of the demolition of a wall, whichhad been torn down without its insufficiency having been determined upon a hearing of both parties. This point was recently decided in a case of Tait vs. Lamothe in the Court of Queen's Bench, and shows the necessity of never touching a mitoyen wall without proceeding regularly and in order.

Those who own a mitoyen wall are charged with its repair and reconstruction, and only by abandoning all interest in the wall can they rid themselves of this obligation. If, however, the co-proprietor, wishing to abandon, have placed a building against the mitoyen wall he can only abandon by tearing down that part of his building which rests upon the mitoyen wall. Certain authors are of opinion that in order to be rid of the obligation to repair and reconstruct a fence wall it would be necessary to abandon the whole of the property in question because this obligation is a legal servitude upon the property, and only by giving up all the property can one get rid of it.

The co-proprietor of a mitoyen wall is authorized to execute certain works and is forbidden to execute others.

1. He may build against the common wall.
2. Place beams in it to within 4 inches of its thickness.
3. Raise the common wall, upon paying an indemnity of 1/6 of the value of the superstructure.

In case the wall is not in a condition to support the superstructure, then he who wishes to raise it may demolish it and rebuild at his own cost, and if any additinnal thickness is required he must take the land on his own side. In this case, he will, of course, have no indemnity to pay for the superstructure. On the other hand the neighbor cannot complain of the inconvenience and sometimes serious loss and damage to which he may be put. Thus, for example, A may keep a restaurant, B his neighbor, wishes to raise the common wall, and for that purpose take it down and rebuild it more solidly. A cannot complain even though his restaurant is almost deserted on account of the dust, dirt and noise caused by B, so long as B proceeds with diligence and does what he reasonably can to mitigate the nuisance. This doctrine was laid down by the Court of Queen's Bench in a case of Lyman vs. Peck. (6 L.C.J., p. 214).

Art 517 C.C. provides for the acquisition of the joint ownership in the superstructure by paying half its cost.

Art 518 C.C. provides that a proprietor who wishes to acquire the joint ownership of the whole wall only pays half its value. He is thus in a better position than the man who was already joint owner of part of the wall. Most of the French authors, however, consider that when the superstructure is already old mitoyenneté in it may be acquired by paying half its value.

It has sometimes been debated whether or not Art. 514 and 515 gave a right which could be exercised upon simple notice to the neighbour or whether these cases did not fall into the general rule established by Art. 519, which says: "One neighbour cannot make any recess in the body of a common wall, nor can he apply or rest any work there without the consent of the other, or on his refusal, without having caused to be settled by experts the necessary means to prevent the new work from being injurious to the rights of the other."

There does not seem to me to be any room to doubt that Art. 519 should be followed. The neighbour's consent must be obtained, or experts must be called in to settle the necessary means to prevent the new work from being injurious to the rights of the other.

In the case of Stephens v Walker 6 L. N. p. 286, the court of appeals condemned a proprietor to restore to its former state a wall which he had partly pierced without the consent of the neighbour, and without following the procedure indicated in our article.

On the other hand neither of the neighbours can make any opening in the common wall of any sort whatever, without the consent of the other, and this consent is absolutely necessary, and no judicial decree can be obtained dispensing with it.

Articles 521 et Segg, deal with the question of different stories of a house, common ditches, hedges, trees growing on or near the line.

Article 532 deals with the distance or intermediate works required for certain structures.

Articles 533 et Segg. deal with the question of view on the property of a neighbour. One neighbour cannot, without the consent of the other, make in any common wall any window or opening whatever, even if it be made with fixed glass.

Article 534 provides what windows may be placed in a wall, not common, immediately adjoining the neighbour's property. In the case of Cadorette vs. St. Germain (R. J. Q. 4 c.s. 136), our courts held that windows, placed in a wall that was not common, immediately adjoining a neighbour's property, had to be furnished with window sashes (Scelles), and that it was not sufficient that they were simply nailed down. Direct views are only permitted at left from the line, while oblique views must be placed at 2 ft. This distance is measured from the outside surface of the wall, and if there is a balcony, from its outside line.

Oblique views are those obtained by openings in a wall which is perpendicular, or nearly so, to the line separating the two properties. While the question of view on a neighbour's property is a very simple one in theory, at the same time questions of a good deal of difficulty have presented themselves in practice. If, for example, there exist a mitoyen wall between the building which has windows overlooking the neighbour's property, what is the point from which the required distance should be calculated? Evidently it should be from the centre of the wall, but if the wall should not be mitoyen, the distance will be calculated from its outside edge. But what, if later on, the neighbour, exercising his right, acquires the common ownership in the wall? Must the proprietor then close his windows

which would then be within the prohibited distances? The answer would be no. A legal act cannot become illegal by reason of a posterior fact.

While the law speaks of adjoining properties, it does not mean to restrict the sense to properties immediately touching each other; and so if there were a narrow strip of ground less than 6 ft. wide, over which there was a right of view, this would not prevent the proprietor of the following piece of property from complaining of views placed at less than 6 ft. from his land. Logically the same rule would apply where two properties were separated by a public road less than 6 ft. wide. All of the authors, however, make an exception of this case.

In a case of Hotte vs. Fauteux R. J. Q. 5 B. R. 38, the question came up as to whether views could be established in a common passage when each of the neighbours had furnished half of the land required for such passage. In this particular instance the passage was 8 ft. wide, and each neighbour had furnished a strip of 4 ft. Under these circumstances the Court of Appeals decided that a servitude of right of way was created, and not a right of co-ownership, and that each neighbour remained owner of the strip of land which he had furnished. The openings being thus within four feet of the neighbour's property were ordered to be suppressed.

Again, supposing for example that the proprietor have placed in the wall, which is not common, such openings as the law allows him to place, and that later on his neighbour acquires the mitoyenneté of it, can he be forced to close these openings? The authors are divided upon the question, but it would seem fairer to consider that the neighbour acquiring common ownership should take the wall in the condition in which he finds it.

Servitudes established by the act of man.

These servitudes are divided into three classes:—

1. Urban and rural.
2. continuous and discontinuous.
3. Apparent and non-apparent.

Urban servitudes are those established for the use of buildings whereever situated. Rural servitudes are those established for the use of land.

Continuous servitudes are those which can be exercised without the actual intervention of man, such as rights of view, etc. Discontinuous servitudes are those which require the actual intervention of man for their exercise, such as rights of way, etc. Apparent servitudes are those which are manifest by external sign, such, for instance, as a right of way made apparent by a gateway.

In order that a servitude which is discontinuous and non-apparent shall be binding upon subsequent owners of the property, it must be registered in the registry office of the division in which the property is situated.

There is a good deal of jurisprudence upon this point inas much as the courts are called upon to appreciate questions of fact, thus for example it has been held that a right of way is rendered apparent by the existence of a gate in the fence which separated the dominant and servient tenements and consequently the registration of such right was not necessary. On the other hand, it has also been decided that a pipe, placed in the earth for conducting water, when it is covered with earth and especially when the earth itself is covered with snow, being non-apparent the servitude which might exist in respect of it is equally, at that moment non apparent. These questions, however, are matters of fact which must be left to the appreciation of the court.

Servitudes are established by express title or by what is called "Destination de père de famille." As we have seen, no servitude can be acquired without a title and the principle that the acquisition of a servitude cannot have possession for its basis has been affirmed in the Supreme Court as well as in our own Provincial Courts. (Jones vs. Fisher, 17 Sp. C.R. 513.)

Now what is meant by "Destination de pere de famille"? It may be defined thus, the disposition and arrangement that a proprietor makes and by reason of which one of the properties or a part of one property, is destined for the service of the other. So for example, if there were two houses belonging to the same proprietor, the drainage from one of which passed over the land occupied by the other, and later on these two houses fell into the hands of different heirs, there would be a servitude established in favor of one of these properties over the other to allow such drainage to pass off in the manner in which it had done when they both belonged to the same proprietor.

Two things then are necessary, possession of two properties by one proprietor, arrangement during possession and by that proprietor, which would constitute a servitude if the property belonged to two different owners. According to the old custom this "destination de pere de famille" is equivalent to title."

Generally speaking the establishment of a servitude implies the concession of all that is necessary to put it to practical use. Thus for example a servitude of drawing water would carry with it an implied right of way. So also the owner of the dominant tenement would have the right to make, even upon the property of the servient tenement, all works necessary for its exercise and preservation, while on the other hand the proprietor of the servient tenement must do nothing which might tend to diminish the use of the servitude or render it more inconvenient; the owner of the dominant tenement must on his part do nothing which would aggravate it.

The question of diminution or aggravation of a servitude is one of fact to be determined by the courts.

Servitudes become extinct by confusion, that is to say, when one and the same person becomes owner of both the dominant and servient tenements. It is evident that a man cannot have a servitude over his own property.

Non usage for 30 years will also bring about the extinction of the servitude. In respect of discontinuous servitudes having need for their exercise of the actual intervention of man, so soon as this intervention ceases there is non usage, so that the 30 years would begin to run from this last exercise of the servitude.

As to continuous servitudes whose existence is independent of the intervention of man inaction could not constitute non usage. There must be an act contrary to the exercise of the servitude, that is to say, which would place the servient tenement in a condition of liberty. For example the servitude of right of view would not be interrupted by the fact that you kept your windows closed for it consists in the existence of these very windows. But if, on the other hand, you filled in your windows or if your neighbor built a wall which completely obstructed the view, then there would be non usage and consequently extinction of the servitude if you allowed this state of affairs to continue for 30 years without action on your part.

RISK.

The second part of our subject to-night deals with "Risk". It is hardly necessary for me to point out how important this question is from a practical point of view. For example in case the thing be destroyed before acceptance by the master, upon whom does the loss fall, or if the master become insolvent before completion of the work, in what position is his estate, or if the master were married while a building destined for him was in course of erection, does such building fall into the community or not?

The articles of our code which deal with the subject are 1683-4-5-6-7. The general maxim of law which must govern all questions under these articles is this "Res perit domino", that is to say a thing perishes for the owner. Whoever was the owner of any particular thing at the time of its destruction must suffer its loss. This rule, of course, does not deprive the owner of his recourse against him who caused the loss, if fault is attributable to him. Now article 1684 says:—

(1684.) "If the workman furnish the materials, and the work is to be perfected and delivered as a whole, at a fixed price, the loss of the thing, in any manner whatsoever, before delivery, falls upon himself, unless the loss is caused by the fault of the owner or he is in default of receiving the thing."

This is practically a sale of the thing subject to verification by the owner It is a sale of a thing to be made—consequently the sale of a future thing and so a conditional sale. The sale is made under the condition that the object which will be presented by the workman will be properly made. This condition is fulfilled when the thing is verified and accepted by the master. From this moment the risk of loss falls upon the master and not upon the workman. While the code speaks of "Delivery" the authors are agreed that verification and acceptation are all that is necessary and that after that, the workman holds the thing for the account of the master.

If the master be in default to receive it the risk also falls on him, as he has prevented the happening of the condition, because article 1084 C. C. says that a conditional obligation becomes absolute, when the party bound under the condition prevents the fulfillment of it.

Articles 1685-1686 say:—

(1685.) "If the workman furnish only labor and skill, the loss of the thing before delivery does not fall upon him unless it is caused by his fault."

(1686.) "In the case of the last preceding article, if the work is to be perfected and delivered as a whole and the thing perish before the work has been received, and without the owner being in default of receiving it, the workman cannot claim his wages, although he be without fault; unless the thing has perished by reason of defect in the materials, or by the fault of the owner.

When therefore the master furnishes the materials, then cases arise, (1) The thing perishes by the fault of the workman—he will owe its value to the master and may be held in damages. (2) The things perishes by fortuitous event—the master loses his materials and the workman loses his work. (3) The thing perishes through a defect in material, the master loses his material, but the workman has a right to be paid the price of his work. We must, however, make an exception to this rule, of the case

where the workman by reason of his profession should have known of the defect in the material and should have notified the proprietor. Such for example would be the case of a builder employing defective timber where he should have known better.

Could the workman claim the price of his work done at the moment of the loss of the thing? Yes, if the accident happened after the work was accepted by the master. No, if the loss occured before acceptance. Those who support this doctrine say that the workman has only a right to be paid in so far as the work was well done and that since the thing has perished, the verification of this fact has become impossible. It is urged also that this solution is only an application of the maxim "Res perit domino", that the workman is still owner of his work until it has been accepted. He has not only promised his work, but he has promised to make it so as to be received, that is to say to deliver it to the master. Until such time he is owner of it and consequently loses it, if the thing perish.

This is the position taken by the commentators of the Code Napoleon. The commissioners who drew up our code, after careful thought, adopted textually the articles of the Code Napoleon. At the same time they have not indicated them as being new law. Now there is no possible doubt that the Roman Law and Pothier did not adopt such a solution. The Roman Law and our old law before the code, was in the sense that if the work was such that it should have been accepted, then the master must suffer the loss of the materials, and pay the price of the work. The proof of the work being well done would be on the workman, but if he could make such proof he was to be paid. Such was the law before the code. It has been urged that our codifiers intended to reproduce that law. Under the strict wording of Art 1686 and in view of the fact that it has been taken textually from the Code Napoleon, I do not see how we can do otherwise than accept it as being our law, and consequently reject the solution of the Roman Law and the old law. We have been dealing hitherto with moveables, we come now to the more important question of immoveables. Do articles 1684 and 1686 apply to Architects and Builders? Are they included in the term "workman?" In the cases which we have been discussing does the architect lose the value of his services and the builder his materials and labor? As is natural upon so important a question there is diversity of opinion.

The Roman Law considered that where the owner furnished the land, whatever was built on the land acceded to it and became his property by right of accession. They therefore applied the maxim, 'Res perit domino,' 'a thing perishes for the owner,' and concluded that the owner must suffer the loss of the materials which had gone into the building and must pay the builder according to the work done. This also seems to have been the view taken by the old law before the Code. Pothier, treating of this subject says, "Supposing I have made a contract with an architect to build me a house on my property, for which he is to furnish the material. So fast as the building is erected it becomes an accessory of my ground. All that results from the work of the architect, the materials furnished and the form given to them belongs to me by right of accession. The loss is consequently mine, if it perish accidentally. The commentators of the Code Napoleon have considered that these articles were equally applicable to architects and builders, and that until the building was accepted its loss fell upon them. There is no valid reason for excluding architects and builders from their provisions, and even if you did do so you would still fall under the general rule, 'res perit domino,' and then if you considered the builder still the owner of the materials until their reception, the loss would be his.

It is said in answer to the argument that the materials accede to the soil, and consequently belong to the proprietor by right of accession, that accession is not accomplished against the will of the proprietor, and that these materials are only conditionally his property, and cannot be at his risk. La Cour de Cassation, the highest court in France, has adopted the reasoning, and, so far as the Code Napoleon is concerned, such seems undoubtedly to be the law. As a matter of fact, both the Roman law and the French law have exactly the same point of departure in the maxim 'res perit domino,' the effect, however, which they have each given to it has been different. The Roman law found the owner in the master, by right of accession. The French law found the owner in the workman, by right of an implied contract by which the master only became owner after the work had been received by him, thus seeing an intention in the parties to override the general principle of accession.

Has our code adopted the solution of the Code Napoleon? We have seen that it has adopted the exact wording of its text, and it would seem to me that unless we can find some very good reason in the codifier's report for believing that they did not intend such to be the solution under our code, that we must take it as it stands and join hands with the French authors.

An examination of the codifier's report makes it perfectly plain that they did so intend to adopt the Code Napoleon.

We are therefore forced to the conclusion that the building is at the risk of the builder until its acceptation, or until the owner is in default to receive it. The principles governing the contract of lease and hire of work apply, and not those governing the right of accession.

Two cases recently decided by our Court of King's Bench leave no doubt upon the point. I refer to the case of Murphy v Forget and Lessard v Shallow. In both these cases the court decided that these articles apply to architects and builders. They adopt the Code Napoleon and say that the contract is governed not by the rules of accession but by those governing the contract of lonage d'ouvrage.

NOTES.

A correspondent writes the London Builders' Journal to know whether he should come to Canada for employment at his trade as carpenter and joiner or join the army. The Journal advises hime to come to Canada where he will have plenty of scope and opportunity to start in business for himself.

Ochre has frequently been recommended as a primer for use under subsequent coats of white lead. While it has undoubtedly the property of holding fast to wood itself, it does not hold as well to the white lead coats, which sometimes separate from it in flakes. This could probably be avoided by the addition of a certain proportion of white lead to the ochre for the priming coat.

AN EXPLANATION.

NEW YORK, June 7th, 1904

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—As a means of justifying ourselves and correcting a false impression, we would ask you to publish this letter in a conspicuous place in your magazine.

There appears to have been circulated in Montreal a false, as well as unjust and spiteful rumor as to our standing and methods of doing business. This is evidently the result either of a row between two parties who agreed to act in conjunction as our agents there, or else the result of a spiteful feeling on the part of one of the above mentioned individuals, because of our having refused to continue business relations after our experience with his firm on the subject of payment of duties and delivering in which they were guilty of gross errors and misrepresentations too serious to cite.

We are not interested in family rows, nor do we care to slap back, for we might be able to hit too hard; but we want it thoroughly understood in Montreal in particular and Canada in general.

1st.—That we were the first to show American goods in our line, could be sold and delivered with eminent satisfaction to the Canadian market, and ours in particular, cheaper and better than any others.

2nd.—That we are in the Canadian market to stay, and to prove to the best builders and architects that we are A1 in finance, ability, delivery and product, and the right kind of people to deal with. We refer to a wide and long range of architects and builders during ten years active work, a list of which will be furnished on application.

In Montreal we are now represented by T. A. Morrison & Company; in Toronto by our old friends J. D. Macdonell & Company, both representatives of the best the trade offers.

Extensive photos of past work in detail, in album form, a practical and technical catalogue; samples and prices; and a printed and classified list of users of over ten million of our brick in the States; and a stock-list of brick, close up to two million are ready to be placed at the disposal of Canadian architects or builders who wish to be convinced of our standing. We invite inspection of our Canadian deliveries as compared with those of other manufacturers, including English and Scotch.

Very truly yours,

AMERICAN ENAMELLED BRICK & TILE CO.

J. Francis Booraem, Mgr.

SOURCES OF HEAT.

Faraday calculated that the average amount of heat radiated in a day on each acre of ground in the latitude of London is equal to that which would be produced by the combustion of sixty sacks of coal.

The heat of our globe is termed terrestrial heat. The layer of constant annual temperature is the limit to which the solar heat can penetrate below a certain internal layer. Its depth varies in different parts of the globe; at Paris, it is about 30 yards with a constant temperature of 11.8° C.

The temperature increases below the layer of constant temperature at the rate of 1° C for every 90 feet on the average. The greatest increase is at Irkutak, in Siberia, where it is 1° for 20 feet, and the lowest is in the mines at Mansfield, England, about 1° C. for 330 feet. This central heat is confirmed by the existence of hot springs and volcanoes.

To account for the existence of this central heat, various hypotheses have been proposed. The one usually adopted by physicists is that the earth was originally in a liquid state in consequence of the high temperature and that by radiation, the surface was gradually solidified, so as to form a solid crust.—Engineering Review.

Fire at Tyndall, Man., recently destroyed the engine shed of Gunn & Co.'s quarry, also the switching locomotive used in connection.

NOTES.

Water was first brought into London dwelling houses by lead pipes in 1582, by Peter Morris, a Dutchman.

Two Canadian patents for fireproof construction have recently been granted. The main feature of one is a network of wires or rods, fastened with hooks to supporting beams, and covered with a reticulated material; concrete is then placed on top of the beams, rods and this material, and above that are placed alternate layers of felt paper and insulating material, and the floor is laid on top of them. The other patent consists of a fireproof tower containing ventilating shafts, in connection with a system of water-pipes arranged in the ventilating shafts and within recesses in the floor of the building. Other inventions are a device for removing shingles and a tiled flooring.

The Japenese houses extend from the magnificent types of towers known as 'pagodas' to the plain dwelling. Some of these dwellings, however, are exceedingly elaborate in structure, the tile roofing often being highly colored. The coloring materials are made into the clay stuffs at the works, and the color is therefore fixed and lasting, even under the influences of the sun and the rains. Many of the low buildings are erected with an unusually rigid framework, which is built in with the clay cubes, bricks and tilework. The 'cage' construction of house building is followed quite closely, and one sees many a little Japanese habitation, in which the tiny apartments are erected with heavy walls, very clumsy and thick but essentially substantial. Much of the timber work is round, and the connections are with mortise joints pinned together. The roof is trussed and commonly tiled.

FIRE-PROOF GLASS WINDOWS

THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

A Hint About Planning.

A weak point in the planning of perhaps the majority of modern houses will be found to be the arrangement of the top or "attic" storey. These upper storey rooms might be made both comfortable and attractive, if they were given due consideration by the architect. As a rule they either do not seem to receive the attention to which they are entitled, or are sacrificed for the sake of exterior effect.

Compulsory Ventilation.

The Legislature of the state of New York at its last session passed a bill providing for the ventilation of public buildings and having particular application to school buildings. This is the first comprehensive measure for the purpose yet adopted in the United States. In seventeen States, however, laws have been passed which require expert examinations of plans for projected school buildings and provide for fire scapes and other means of protection from fire.

The Architect and the Contractor.

The production of a satisfactory building requires the best efforts of both architect and contractor. The architect needs the sympathetic co-operation of the contractor, and to this end should seek to maintain harmonious relations. The honest, intelligent contractor—and there are thousands such—is, in his field of effort, as important a man as is the architect in his. He is therefore entitled to be treated by the architect with courtesy and respect. Unfortunately some architects, possessed of an undue sense of their own importance, are in the habit of treating contractors in a most arbitrary and discourteous manner. In the west, where the democratic feeling is strong, an eastern architect who assumed this offensive manner was promptly taken to task by a prominent contractor and in unmistakeable language told that such treatment would not be tolerated. Where contractors show a disposition to evade the strict terms of their agreements, the architect is justified in being severe, and indeed will show wisdom by refusing to have any further dealings with a contractor who has forfeited his confidence. But with the honest contractor the "high and mighty" air is unjustifiable, besides being calculated to bring the architect and his authority into disrespect and stand in the way of the successful working out of his designs.

The Union Label on Buildings.

In proposing that all buildings erected by union labor should be labelled, the National Building Trades Council submit as a reason the following:—"The union label on a building will be a testimonial that the men who erected the building are thorough mechanics earning fair wages, and thus enabled to benefit the community as consumers. It will be the

best guarantee that the building is safe, substantial and in a sanitary condition." The contention here made is not capable of proof, and is advanced in the hope that it may serve to obscure the real object in view. While it is doubtless true that a majority of the most skilled workmen may be found in the union ranks, it is by no means the fact that none but good workmen are admitted. There are thousands of incompetent workmen belonging to the unions, and conversely, there are many first-class mechanics who are non-unionists. Hence it follows that the employment of only union labor is not in itself a guarantee of good workmanship. One of the most serious and well-founded complaints preferred against unionism is that it has done nothing to raise the standard of workmanship, but on the contrary seeks to place all mechanics on one level, disregarding the widely differing abilities with which the Creator has endowed them.

Uniform Cement Specifications.

Official or quasi-official specifications governing the character of cement for construction work have been adopted in Germany, France, Sweden, Switzerland and Russia. An attempt to standardize specifications is now being made in England, where, at present, as in Canada, specifications vary widely even where the nature of the work and the conditions are identical. According to a recent writer on this subject some English cement specifications call for 300 lbs. per square inch on the neat briquette after 28 days; others demand 550 lbs. after 7 days. Not only are different specifications inconsistent with one another (assuming that the architects and engineers who drew them were anxious to obtain good cement) but they often themselves contain paragraphs mutually inconsistent. Such for instance, as finely ground cement with an extreme weight per bushel. Some time ago, says the writer, an engineer drew up an elaborate document giving, amongst other things, the size of the sieve wires. Upon investigation it was found that had the sizes he specified been adopted the cement would have had to find its way through a solid brass plate. As we have previously pointed out the extensive use which is already being made of cement in construction and the certainty of its employment on a still more extended scale in the future demands not only properly drawn specifications, but also a system of testing all cement, in order that the safety and durability of structures built largely or entirely of this material may be assured.

Only the Best is Wanted

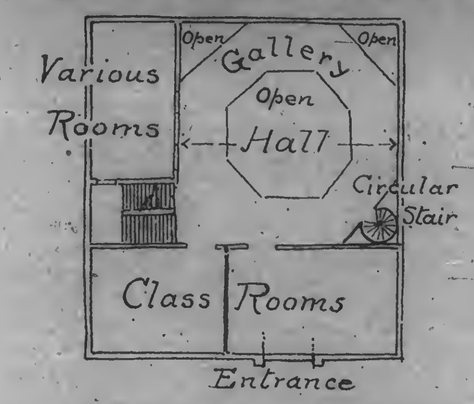
Manufacturing methods have greatly improved in recent years. The production by enterprising firms of goods possessing not only high quality but artistic design and pleasing appearance, has created a demand on the part of purchasers which cannot be met by the manufacturer who seeks to stand by old methods and styles. The manufacturer who is not prepared to bring his goods up to the highest standard in every particular had better retire from the field, and not wait to be forced out by his more enterprising competitors. Some manufacturers enter upon the manufacture of a certain line of goods as a side line to what they regard as their principal business. This side line fails to receive the careful attention and push that is given to the other departments of the business and in consequence drags along in a lifeless sort of way, the goods produced being regarded with disfavor, and failing to hold their own in the market. In perhaps no other direction has there been greater progress than in the production of materials adapted for use in the construction and furnishing of modern buildings. A remarkable improvement is manifest in our modern Canadian architecture, more particularly our houses. The new requirements make constant calls upon the manufacturer for new and improved materials. Whether his business be to make bricks, radiators, plumbing goods, or the thousand and one other materials used in modern buildings, he can only hope to succeed by keeping his goods in point of qual- and appearance thoroughly abreast of modern requirements.

The Relation of Science to Architecture.

In a recent paper before the architectural Association of London, Mr. A. E. Munby urges the necessity of giving the study of science a larger place in the education of architectural students. He reminds us that the modern building and its equipment involves many scientific features and problems with which architects in the past had not deal but with which the modern architect must be familiar. There are also constantly being brought forward scientific inventions for use in bnildings upon the merits of which the architect should be competent to decide. Mr. Munby points out that if the architect has not the scientific knowledge to enable him to do this, or having the knowledge, shows indifference to such attempts in the direction of progress, it ought not to cause wonder or complaint that the tide, stemmed by his apathy, finds new outlets, and that the public place in other hands matters which should pass through his hands alone. The author quotes the saying of Ruskin that "Every work of art either states a true thing or adorns a serviceable one," as proof that there is no conflict between art and science. After showing some of the most important applications to architecture, he concludes by suggesting that a passage through the following courses should form part of the requirements of an architectural student at the outset of his career: (1) A general experimental course on physics, including laboratory work and dealing with the dynamics of solids and fluids, with heat, magnetism and electricity, and very briefly with acoustics and optics; (2) A similar course dealing with the elements of inorganic chemistry, touching upon principles, but chiefly of a descriptive character. Mere analysis to be subordinated to simple quantitative work and the preparation of important compounds. The illustrations of chemical laws being based, as far as possible, upon those substances which would afterwards figure in a course of applied chemistry; (3) A short course outlining the principles of geology, and dealing with the stratigraphical arrangement of rocks and with petrology rather than with palaontology, and aided by the examination of museum specimens, and by occasional visits to quarries. The paper contains a table showing the hours per week devoted to science in the Architectural Courses in a number of Universities in Europe and America. At the head of the list stands McGill University of Montreal, with a total average of 79 or 30½ per cent. of the student's acadamic career devoted to science and its applications.

THE ARCHITECTURAL ASSOCIATION AND ITS WORK.

A visit to the new building of the Architectural Association showed that they are doing real work, worth studying. Their new quarters are in the building of the Royal Architectural Museum at Westminster which, with the architectural casts it contained, was handed over to the Association about a year ago; and the Association have, in the meantime, spent over $40,000 in altering and adding to the building, to fit it for their use. The result is a building composed of three divisions, each containing one set of the Association requirements, and a staircase in an angle between them.



There is first, for the disposition of the casts of the architectural museum, a hall about 50 feet square and three stories high, open to a skylight but with a ten-foot gallery running round it at the floor levels. On a third side are the staircase and a small block of rooms for general purposes—a dining or common room with serving room attached, the master's room, a coat room, lavatories, etc., and the front, which is four storeys high, is taken up with the library rooms and the secretary's room on the ground floor at the entrance and three floors of class or lecture rooms above. The two top floors are each divided into two class rooms; one floor for the day school, the other for the evening school, each of which consist of two classes. The first floor is divisible into three rooms by means of folding partitions or can be opened up into one large hall about 70 feet long and 24 feet wide.

So much for the habitation. The works are numerous. What concerns us most is the school work. There are three divisions: the Day School, the Evening School and the School of Design.

The Day School. This school which begins its year on September 28th and ends it on July 16th, has three terms of twelve weeks each with hour from 9.45 a.m. to 5 p.m. The fee is 15 guineas a term ($228.70 a year) for the first year and 10 guineas a term ($152.50 a year) for the second year. There is a master, who directs and attends to give lectures, and two assistants who are always in attendance. The subject matter of the teaching is the elements of construction and design. There are two years. The first year is preliminary to articles, intended to give the student a standing of some usefulness when he first enters an office, and to fit him to understand better and learn more rapidly from the work he will see going on about him. The second year is taken in connection with office work; a certain portion of his time during his first year in articles being allowed the student for school work.

In the first year all the ground is covered, in both history and construction. The master gives a lecture a week in each subject and the rest of the time is occupied by drawing under the direction of the demonstrator. The following is an outline of the work:—

Construction is taught by means of visits to buildings in course of erection. It does not require many visits in a term, for the subdivisions of elementary construction when spread over three terms, do not give too much to think of at one time. The subject is divided as follows: First term, Foundations, Brickwork and Masonry; second term, Timber and Metal Construction; third term, Roof Coverings, Plumbing (which is English for flashing and flat work, as the work is usually done in lead), Plastering, Joinery and Finishing. The method of teaching is to first explain construction on a building, with examples before the students of the points under consideration, and then to set papers to find out how much they have learned as a guide to further lectures. Drawing goes on concurrently with lectures, and there is a blackboard upon which the students are encouraged to study details full size. A case of models comes into use in the last term when joinery and other finish is under consideration. By that time the drawing has reached the stage of application, still however only by means of copying drawings. Drawings of a cottage are supplied for study and imitation; large and small scale drawings and full sizes are drawn, traced, printed and colored, and specifications are written, exactly as would be required in an office. The year's work in the study of Construction thus brings the students into touch with actual draughtsman's work.

On the side of History there is outside work to be done both on buildings and, for the earlier stages especially, in museums; but drawings play the principal part. Beginning with the Orders, the students proceed, during the first term, to the study of a large Roman plan, exemplified by the Baths of Caracalla, photographs of which in its existing state and a drawing of its conjectoral restoration hang on the walls to help them to realize the building. Roman basilicas wooden roofed and vaulted conclude the the first term's work and prepare for the second which is occupied with vaulted buildings—a plan section and elevation of a Byzantine and a Romanesque church and a couple of bays of an early-French vaulted refectory. In the third term the students work through the more elaborate Gothic vaulting to the Renaissance, which they study in English examples. Lectures in the meantime go on, keeping pace in subject with the period of the drawing in hand, and the object of the lectures is not so much to carry on the same line of instruction as is given by drawings as to give an account of the history of the period and cast light on the manners and conditions of life which gave rise to the style of building under consideration at the moment on the drawing boards.

During the first year there is also given some instruction in measuring old work, and the Easter vacation of a month is supposed to produce a study of this kind; for which opportunities of such work with prizes and rewards, offered later in the students' career as members of the Association, give sufficient inducement.

At the end of this year's work a student should be fairly qualified, in point of both construction and de-

sign, to be useful in an office and to learn from office work. There is also a chance that, without spending more than a year over it, he will discover that he is not fitted for such work at all. Unless this discovery is made, he is supposed, on the conclusion of the first year of the Day School, to enter into articles with an architect for an apprenticeship of five years. This is usually done at once; and in the autumn he resumes work in the Day School, which in this year is limited to two days a week.

The work of the second year consists entirely of working out problems in design from specified conditions. There are no lectures; instruction is given by criticism. The distinction between the work done by this class and that of the studios and Sketch Clubs for more advanced students, with which we have some acquaintance in Canada, lies in the motive. It is a first principle of the training for an art that the mind should not be led beyond the hand, and there is no attempt made in this class to develop individual invention; the intention is rather to make the design merely a vehicle for working into form what the students have learned in their previous year's study of the History of Architecture. It is one thing to be familiar with detached features of historical design, or even to draw them in place, and another to understand or remember their characteristics well enough to apply them in work of one's own composition; and the problems worked out in this class serve to clinch the student's knowledge of style by giving them experience of its practical application. The library of the Association furnishes them with the means of accurate study so that there is no reason why they should not, between study and criticism, build up a design which is scholarly and yet original in the sense that they have made the knowledge which it represents their own. The great divisions of style receive equal attention so that no bias is acquired in the school towards one more than another. Construction is represented by a domestic problem or two of a simple nature for which drawings and specifications sufficient for contract are made.

This ends the work of the Day School. To carry his learning farther the student must attend the Evening School intended for pupils who have passed their first year and have to spend all their time during the day in an office.

It will be necessary to take the space of a second article to give an account of this and the other proceedings of the Association.

W. A. LANGTON.

THE SELECTION OF COLORS.

The following table will be found useful in choosing the various tints, inasmuch as by examining them in the order here given the eye will at once detect the slightest difference of shade. To refresh the eye

Look at	Greens	before choosing	Reds.
"	Blues	" "	Oranges.
"	Violets	" "	Yellows.
"	Reds	" "	Greens.
"	Oranges	" "	Blues.
"	Yellows	" "	Violets.

Steel tapes are graduated in feet and tenths, and pocket tapes to hundredths of a foot.

BY THE WAY.

In the tower of the Central Methodist church on Bloor street east, Toronto, now in process of demolition, hung for half a century or more the town bell of Yorkville, now included in that part of Toronto lying north of Bloor street. The bell has been temporarily taken down but will again be mounted in the new tower of the reconstructed church.

It is reported that the Treasury Department at Washington is about to issue an order prohibiting draughtsmen in the employ of the Government from making drawings for outside firms. It is estimated that fully one-half of the 150 draughtsmen employed in the office of the supervising architect of the Treasury give their services after hours to outside employment, and this it is held interferes with their efficiency in the Government service. This practice has also prevailed in Canada, and has been the cause of protest from architects in private practice who felt that they were being subjected to unfair competition.

× × ×

A Japanese house is the simplest thing in the world, says a writer in the Western Architect, consisting as it does of a post at each corner and a roof. One may say it is all on one floor. And in the daytime it is all one room, if it is a small house. The number of bedrooms in it depends on the number of bedrooms the ower requires. They are divided by night by paper shutters fixed in grooves like the divisions of an old-fashioned workbox. There are no doors or passages. Your bedroom acts as a passage, and when you want a door you slide back the nearest panel. Two sets of shutters go around the outside. These outside shutters cannot be slid in the same promiscuous fashion as the other. Each is held in its place by the next and the last one is secured with a bolt of wood. There are plenty of Japanese houses which when secured for the night would hardly stand a drunken man leaning against them. An Englishman's house may be his castle—a Japanese house is his bedroom, and his bedroom a passage.

× × ×

There died at Philadelphia recently a wealthy stone merchant, William Gray, who was at one time well known in Bruce and Huron. In 1871 he came to Canada and settled near Iverhuron, in Bruce Township. There he was known as Boss Gray, and there he carried on extensive operations. On the second concession of this township he bought a farm of two hundred acres, and built a great stone castle. A fine avenue, bordered by spreading trees upon either side, led up to the magnificent residence. The house was richly and elaborately furnished. In each room mirrors ran from floor to ceiling. There were grand stairways. There were broad and spacious halls. There were wide, open fireplaces. In every room the generosity and the luxury of wealth was artistically exhibited. But it was occupied for only two years, and ever since the rats have run riot through its splendid chambers. When the family left the house the rich furnishings were left behind. Nothing was disturbed, nothing removed. The house has seemed to stand through all these years waiting for the family to come home. But lately the bedding and the curtains dropped to pieces and decay was upon all within the mansion. Grass and weeds possessed the wide avenue, the trees were ragged with neglect, and the gate sagged upon its hinges.

NORTHWEST NOTES

Branch Office of THE CANADIAN ARCHITECT AND BUILDER,
310 McIntyre Block, WINNIPEG, July 14, 1904.

The progress of the many building propositions continues apace. Contractors on every hand are making the most of the excellent run of fine weather we have recently had, and had it been possible to have obtained a full supply of materials, greater headway would have been made and much more satisfaction to all sections of the community have resulted. As it is, however, building operations are sadly in arrears of the positive necessities of the immediate demands. Offices, warehouses and dwellings are alike pressing their needs to the front and vying with one another for first attention.

Office space in any desirable location is almost impossible to obtain, and in the event of any office being vacated plenty of occupants are readily forthcoming, and rents are consequently going up with leaps and bounds. The conveniences, too, of many of these buildings are sadly deficient, and no attempt is being made to give attention to the many modern and necessary improvements which in most other cities are considered part and parcel of an office equipment.

The new Union Bank Building, which is now well on in its construction, is looked to as providing a decided relief in both these respects. Besides placing at disposal a large number of additional offices, it will also have the advantage of being thoroughly up-to-date, and on this account many firms have secured space and are leaving offices which they have occupied for a great while, and the inconveniences of which have had to be endured.

We should judge there never was a better opportunity than the present for experienced and enterprising men to make capital for themselves and at the same time confer a distinct benefit on the hundreds of business firms which are looking to the West for development of their commerce, by the erection of buildings of the most modern type and adapted to the conditions prevalent in the district. And this would apply not only to the class of buildings just mentioned, but to all buildings for which there is a demand. There is clearly manifest on every hand a great tendency to erect buildings sadly deficient in their details of construction and finish. The mad rush of buyers has brought on the market a number of men whose sole endeavor is to get a building together at as little cost as possible, even though it be at the sacrifice of, what should be, necessary details, the number of people seeking dwellings making it an easy matter to secure purchasers. It is true many of these men are "small" men, and act as their own architects, but the real injury is certainly not minimized on that account, but rather increased, as they have neither the reputation of the architect at stake, nor the stability of a sound builder to fall back upon.

"A straw will show which way the wind blows," and there are already whispers that the capitalists are beginning to limit their advances on certain classes of properties and in order to complete sales builders have had to take certain risks on the mortgage—a clear indication that present values are questionable.

The foregoing remarks will, of course, apply more particularly to houses built expressly for sale, but inasmuch as the prosperity of Winnipeg has come to stay, it is of the first importance to see that its buildings are such as will become a sound investment and not a source of trouble.

There is really no reason why there should be any difficulty in this respect. Winnipeg possesses at the present time as competent a staff of architects and contractors as could be desired; it would therefore be an easy matter for a prospective buyer to obtain a concise and accurate report of any building, from a man of professional repute, for a charge that would be infinitesimal compared to the immense advantage of such a certificate. At the present time, however, it would appear that all these necessary precautions are at a discount—so great has been the boom, and so eager the purchaser, that their best interests have been neglected.

The need of a precaution of this nature becomes the more apparent when the fact is taken into consideration that the "by-law" which governs the erection of buildings is considered to be of a most unsatisfactory nature, leaving as it does the interpretation of what a "foundation" really is according to the by-law as uncertain and vague as it could well be, so that the unscrupulous builder can steer well within the letter and still miss the real benefits which it is meant to confer, and the evils it was intended to remove. As long as he lays a simple stone or cement footing upon which to erect his structure, he is well within the "by-law," the question of going deep enough to strike the solid blue clay being left entirely to the discretion or whim of the builder himself. And this too within the protected limits of the city.

In our last issue we pointed out one of the peculiarities of the soil here in this city, and with this before the mind it can easily be seen the great danger that exists where a proper solid foundation is not reached.

A man building for his own holding will, of course, be amply protected by his architect, and there is little danger in that case; but for the buyer from a speculative builder a certificate from a professional man becomes an absolute necessary precaution.

We understand that a revised by-law is under consideration which will fully meet this unsatisfactory condition, but in the meantime property is being rushed forward, and too great care cannot be exercised in a thorough examination before purchasing.

We note with satisfaction that the authorities are doing all in their power under the present by-law to secure the stability of all new buildings, within the First and Second limits, and are also extending such limits from time to time as occasion requires, thus giving the greatest protection possible to the city proper.

The "First" limit practically includes the whole of the business centre, whilst the "Second" limit comprises the residential section immediately adjoining.

Buildings within the "first" limit are required to be either stone, solid brick, or iron throughout.

Buildings within the "second" limit must be either brick-veneer, metal-clad, or rough-cast.

All roofs in both limits to be of "incombustible" materials or shingles laid in "half inch" of lime mortar.

As an indication of the proportions reached by the enormous influx of population, it might be instructive to note the prices recently reached in real estate values, as compared to those prevailing within a reasonable time.

In the west part of the city, a district which is fast gaining in popularity as a residential section, small plots which last autumn could have been readily bought for $350 have recently changed hands at $550. This is in part owing to the belief that it is at this point that the G.T.R. is likely to locate itself.

In the south advances have been even more marked, the city having pushed out in that direction in a decided manner, and also on account of the close proximity of two public parks. Here the values have risen from $50 per foot to $100 within the twelve months.

In the city proper the advances have been beyond all expectations; property which could not move an offer at $380 per foot last year, has recently been sold at $1,000 per foot. This in itself may be a special instance, but at the same time it is quite reasonable to fix the average advance at an easy 75 per cent. over last year.

A distinctive mark of Winnipeg and one which gives it its character is its essentially "commercial" aspect. The many buildings which are rising up on every hand carry with them the clear lines of warehouses or stores, and present somewhat of a contrast to the heavy factory buildings of many other cities. It is a "commercial" city more of necessity than of design, and there are few, if any, natural advantages which would warrant the supposition that it would ever become a manufacturing centre of any importance. It can easily be seen, therefore, that it is

peculiarly dependent upon outside resources for its supply, and should there arise any cause of interruption in the prompt delivery of those supplies the effect becomes immediately apparent, and the results more serious than otherwise would be the case. In this connection the "freight conditions" of Winnipeg are causing a good deal of dissatisfaction, trade being seriously checked by the uncertainty and delay in delivery of goods. This probably is nowhere more marked than in the building trades, where the scarcity of materials has been causing the greatest anxiety. Many buildings have had to be held in abeyance, and others seriously delayed in their progress entirely for lack of supplies; it is computed that, had there been sufficient materials ready to hand, there would have been an increase of quite 25 per cent. in the completed buildings during the present season; this, in a city where the dearth of available dwellings stands already at almost the famine point, is of most serious moment.

It is without doubt that the present year's progress came as a general surprise; all expected a measure of advancement, but no one looked for such strides as have actually come to pass. The financial section, at the commencement of the year, were inclined to move with caution in face of last year's anticipations not being fully realized, and probably this re-acted on the business men, causing them to hold back many orders which should have gone forward, thus causing a certain amount of delay in commencing operations. The difficulties at the present, however, are more distinctly those of "transit." From all accounts it would appear as though it was high time that a change was made in the handling of merchandise, so that there was some certainty of receiving a consignment of goods within a reasonable time, instead of having to wait and often suspend operations, the only news obtainable being that "the goods cannot be traced." If such a state of things continues, with the present extensive operations under way, it is impossible to tell where it will land us, and a serious check to business will result.

The extensive alterations and improvements to the Exhibition grounds are now rapidly nearing completion, but for some time it seemed as though the buildings could never be finished in time, mainly from the cause already referred to, but by dint of great exertion after much waiting, the work has gone ahead, and will be ready to keep the schedule time.

The tremendous storm which swept over the city some weeks since did a great deal of damage to buildings and property, more especially in the outlying suburbs, and to the smaller new dwellings under construction. In several instances houses were removed several feet from their positions, but without otherwise receiving damage; many simply collapsed with the severity of the wind and a long stretch of sheds on the railroad siding were razed to the ground. On the new Union Bank building work had to be at once suspended owing to the effect of the electricity on the steel work.

If one required additional proof of the real advancement of the city, it could well be found in the excitement prevailing in the community toward the improvement and enlargement of church buildings; there are quite a number in project, and many new ones under consideration. This probably is one of the best indexes to the substantial and financial success of the city; seeing that the churches are to a great extent not only the expression of the religious sentiments of the populace, but also the indication of their social life and progress. On River avenue, Augustine Presbyterian church is nearing completion and will be a fine stone structure in Gothic style, with a seating capacity of upwards of 1100. The Wesleyan church on Juno and William streets is to be improved and the capacity about doubled. The First Baptist church on Hargrave is to have an extensive addition and the seating capacity will be increased by about one-third.

The extension of the city and opening up of new streets and avenues have made it necessary to arrange for a better supply of fire stations. The authorities have therefore derided to erect five new buildings, one on each of the following streets, Sherbrooke, Gertrude, Burrows and McDermott. The plans have been prepared by Messrs. Melville Bros.

The Winnipeg Builders' Exchange held their monthly meeting on Tuesday, the 5th inst. The meeting was a most enthusiastic one and many interesting topics were discussed, a resolution being passed to the effect that each section was to be called together, a permanent chairman appointed, and the arrangements of the section kept in thorough order, preparatory to the adoption of important measures in the interest of the members.

THE BRICK OF WINNIPEG.

The brick supply of Winnipeg is fast becoming a serious proposition. For several months past the greatest difficulty has been experienced in obtaining sufficient to keep work in progress; in point of fact this has been the case since the opening of the season. Work commenced with a short supply and it has been impossible to catch up to the demand. The local brick fields in operation have proved quite inadequate to meet the constantly increasing demand.

There are some ten or twelve brick-yards in full work, carrying some twelve pug mills, and these working at their full capacity produce scarcely 800,000 bricks per day, a total which is greatly insufficient to meet the demand of the building enterprises now on hand, the daily consumption at the present time being probably four times that number.

We understand that several of the largest contracts were originally arranged for Manitoba brick, and it was not until it was found impossible to get a supply on this side that imported brick was resorted to.

In the north end of the city, where a number of small buildings are being erected, the difficulties of obtaining a supply of brick were met in a somewhat novel way. In this district are resident a number of Doukhobors and Italians, and in order to keep up the necessary supply, a gang of these men set to work to collect the clay and mud dug out of the excavations for cellars and foundations, from which they made brick in the crudest and simplest way possible, without recourse to machinery of any kind whatever. The mixing of the clay was accomplished with the naked feet, and the moulding done by hand, the bricks being spread out on the ground to dry, afterwards being stacked in rough kiln fashion in the cellars from which the mud was dug and there baked for use. In this way they have not merely succeeded in keeping enough for foundation work, but have made sufficient to complete a small hotel throughout, for their own local use. The bricks made were at first much larger than usual, and the novelty was by no means reduced in watching the bricks being laid, the workman having to lay down his trowel each time and take up the brick with both hands. It certainly speaks well for the adaptability of these settlers, who had probably never made a brick before in their lives.

The brick in favor in this district is the common white clay brick, and one for which the local clay is particularly suitable. It stands the severe climate remarkably well, and in time gets as hard as stone. However, the clay from which it is made seldom runs at a greater depth than a few feet, and thus makes it a necessity to frequently shift location, a circumstance which prevents the brick-yards from adopting many of the more modern systems, which would probably increase the output.

We understand, too, that at a much greater depth a good supply of fine blue clay can be struck in certain localities, but up to the present it does not appear to have attracted attention, the general disposition being to pass on and keep near the surface.

Last season closed leaving no stock on hand and it looks at present as though this season will close with work standing still for need of brick.

WINNIPEG STONE MASONS AND THEIR DIFFICULTIES.

The present condition of the stone industry cannot by any means be considered satisfactory in Winnipeg and the surrounding districts, not on account of lack in trade prospects, for as for these the possibilities are certainly without limit.

The general rule favoured by Winnipeg architects is to make provision for "native" stone on all heavy buildings, and also on all dwellings of a substantial character, up to the first or second floor lines. This in itself means the absorption of a quantity of stone, mostly of a general and uniform character, so that there would appear to be no valid reason why the production of these blocks should not be continued without any interruption and at a rate which would keep pace with the advancing conditions of the city. Considering, too, that there appears to be ample supply to draw upon, and from all accounts plenty of men to considerably increase the output, it seems the more to be regretted that the present unsatisfactory conditions prevail.

The new Public Library which is well under construction and which should be finished by September next, is one of the greatest sufferers from deficient supply. It is to be almost a stone building throughout, and it is found impossible under present arrangements to obtain sufficient to keep the work going ahead; instead therefore of being "finished" within the specified time, it will be as much as the contractors can do to get the walls and roof up by the time now fixed for finishing.

Other buildings, too, are like sufferers, and perhaps of more importance because of their business character. In every case it means hindrance and check to trade.

It is of significance, as showing the natural result which follows the undue suppression of an industry, that many buildings are being erected in which "terra cotta" is being used in place of stone facings, and on enquiry it is found that this is mainly on account of the impossibility to get stone with any moral probability of having sufficient to complete the building within a reasonable time. The only thing to be done in order to be certain of securing progress is to use a substitute.

In discussing this subject we are approaching one which has underneath the surface a problem which is likely to affect, not merely Winnipeg, but any and every district within the limits of the confederation of the workmen's union. It is therefore well, and we think opportune, to present the dangers which face the forcing of issues on lines at present assumed by the men's union. The common experience of all trades, and we think it should be palpable to the simplest intellect, is that as surely as day follows night, so surely must machinery supplant the simple methods of hand labour. A very short review of any trade or factory which has made headway with any rapidity must convince the most sceptical that the introduction of machinery acts as an incentive and opens up possibilities of extension which would never have been dreamed of under the old conditions, and thus increases instead of decreases the employment of labour.

In opposing the introduction of additional machinery, we think it should be quite clear that the stone workers are really placing a serious obstacle to the advancement of their own industry, as well as hindering the employment of many more men, and probably limiting their own earnings. There could not be a better illustration of this than the present season in Winnipeg. The quantity of stone used could have easily been doubled had it been possible to have obtained it, whereas substitutes have been used from the other side, and money which could have been kept in Canada passed over the border.

Further, and perhaps what is more to the point from a workman's standpoint, is the serious effect on the wage earning capacity which inevitably follows the suppression of any industry, and this is what is really done by refusing machinery—the wage earner being the inevitable sufferer, the substitute which gains the field usually reducing the demand to the lowest possible point.

Right here on the spot one of our leading firms have new and improved machinery set down ready for use at great expense, and they are obliged to let it remain idle or face the question of a strike of men. From every point of view this is much to be deplored, as it really seems to the advantage of all parties interested to place the industry on a footing that will keep it on a par with the progress of kindred trades.

This question is, we understand, one of the principal ones for discussion at the forthcoming conference of the confederated unions at St. Louis, and we hope it will end in a manner to commend universal approval.

MONTREAL NOTES.

No. IV.

The gargoyle's ghost flapped his scaly wings disconsolately and scratched a pointed ear with a well armed left claw. They had set him high on a minster tower in Yorkshire four long centuries ago and more, and he had a taste for noble architecture hammered into him with the blows of the mall which had taught him how to grin and bear wind and weather and keep his tail neatly curled against the cornice on which he lived and to be a proper gargoyle.

When an easterly gale upset the old lead spire he had guarded so long he was involved in the ruin and so his spirit had left the broken fragments of his body in the market place far below and had been blown across the seas even to Montreal, where, finding a congenial atmosphere of thin smoke riven by many steeples he sought a spot on which to rest which might remind him of his former life.

But the sense of fitness and proportion in matters architectural which long connection with a stately pile had bred in his stony heart made it difficult for him to settle down. Zinc parapets gave even to this ghost of a gargoyle a violent sense of insecurity. Often he espied afar off what promised him some semblance of gothic comfort but on closer inspection these turned out to be but hollow shams and faked hypocrisies.

Once in his old life he had heard two students of architecture who had measured him up along with the tower where he dwelt, speak of the glories of the gargoyles of Notre Dame at Paris, and hearing that there was a church of that name he sought it out, hoping to find stony brethren to haunt. But from the bleak desolation of that building he fled dismayed.

Now the gargoyle knew that it was the end and object of his being to praise and magnify the Lord in his own little way, just as it was the purpose of the minster, from which he had fallen, to do so. Thus finding a city with many denominations possessing many building none of which he could conceive of as contributing to the praise and magnification of anyone, he concluded that he had come to a land wherein the Lord is not praised; and as he was only a gargoyle he must make allowance for so grossly unreasonable a deduction. That was why he flapped his wings and scratched his ear in the Place d'Armes on the morning of July 12th, 1904, and here begins the adventure.

Opposite the church he had left was a great and spacious portico and in the centre a door, and devoutly preoccupied men were ascending the steps and entering in. Quoth the Gargoyle's ghost, "Is this also a temple of the Most High?" Being inquisitive though sceptical on the matter he followed the crowd. Now inside the door there were building operations in progress and the Gargoyle's ghost thought "how assiduous are these worshippers entering with serious mein thus early in the morning a building not yet completed." By this time he knew that they were worshippers indeed.

As he passed the inner door a great glory struck his eyes. The floor was white and the ceiling was white and the walls were white, and before him was a row of great shining green granite columns with brazen caps and the bases were of jet black stone and beyond these were more columns yet taller and nobler and a wide space with great windows on the further side. And it took the breath of the Gargoyle's ghost away from him and he hid behind a pillar. But presently he had courage enough to examine the jointing of the stone and the hewer's work and such little matters as he had heard the masons who set him in his place talk of and he found all as it should be and conningly wrought beyond belief.

Then noting that the worshippers stopped not, neither bowed down, he followed boldly on into the great hall. And had he come in by a window he had been annihilated on the spot, so goodly was the place and so full of great majesty, but coming as he did from the proper entrance he experienced only a sense of fine exhiliration which was as the master builders had intended it should be with one entering.

The columns were taller than those without and the caps more wonderfully wrought and the cool rich green of the Vermont granite contrasted nobly with the gilding on the caps. The roof they bore aloft was coffered and embellished with fine gold wrought with a beauty beyond belief, for had not those self same patterns been used by men for 3,000 years and more, and had not all the experience of that long time been brought to bear in proportioning them each to his use and place. And the ghost of the gargoyle knew that "scale is everything," for there had been a big discussion whether 10 or 4 feathers would look best on his wings, and the latter had been decided on. His wings were all right he knew.

The piers of the walls were of Tennesee marble, tooled and not polished, and the color was very tender, and there were panels in the walls of red plaster, and the gargoyle's ghost did not like them at first but when he considered how finely they contrasted with all the other elements of that building he knew that they too were right.

And an altar of green Italian serpentine inlaid with red Belgian marble ran from one end of the Temple to the other and the length of the great hall of the temple was 172 feet and the width 84 feet and height was 56 feet. On the edge of the altar there was a screen of bronze cunningly cast and finished and there was no flaw anywhere and the ghost of the gargoyle wondered and said, "Although this temple is not dedicated to the praise of the Lord, he whom they worship here is a very great power and exactness and precision are of the quality of his perfection."

The priests of that temple sat behind the screen and busied themselves with the offices of the temple and ministered to the people, and he could make nothing of it, for the worship was a real one but unlike anything that had ever taken place at the minster and been discussed by the gargoyles there.

So the ghost of the gargoyle lingered till he was satisfied that it was here that the men of Montreal did their real worship and he concluded that the God must be very great to be worthy of so fine a temple and the devotion of the Montrealers in erecting so noble a pile to his honor touched the heart of the gargoyle.

So he went his way and lodged in a pine on the top of the mountain and considered what it all meant, but of two things only could he be at all certain: First, that the temple was very fair and enduring, and secondly, that what the men of Montreal worshipped in the great hall behind the portico that is opposite to the church of Notre Dame is the chief god of the land and that it is therefore right and proper that his temple should far outshine in splendor and glory any building to the Lord of the old minster.

Yet Gargoyle

THE ARCHITECT AND THE GARDEN.*

The intimate relationship between the house and the garden, and consequently between the house designer or architect and the garden, is almost entirely overlooked by or unknown to the general public. This ignorance may, perhaps, be due to the architect himself, who has in the past failed to make use of opportunities when called in to design a new home or to alter an old one. Architects, as a body, have failed to study garden craft and design, or to realize how great is the connection between house and garden from both the practical and æsthetic point of view. But interest is being aroused, both amongst the public and the profession, in this, to me, most fascinating branch of our art, and it behoves us to be fully prepared with reasons why the architect's jurisdiction should extend to the garden, and to see that our knowledge is founded upon sound principles.

I do not propose to go much into the question of the right or wrong in garden design. I would rather dare to paraphrase Kipling and say, "There are nine and sixty ways of constructing" garden lays, and every single one of them is "right"—so long as we keep before us the spirit of the old English garden, and understand the principles which underlay its formation and development. Perhaps, at the outset, I had better say what I personally conceive those underlying principles to be.

First of all, then, seclusion. For if this was not the great aim of the old gardeners, it is an end which has certainly been attained. The brick wall with its green crusted coping, the close-clipped hedge, defying the prying eyes of the curious, high trellis-work with its entwining creepers, all point to this end, and while serving the useful purpose of giving shelter to fruit and flower, wrap the whole garden with a tranquil air of seclusion, security, and mystery. This was well understood in the seventeenth century, and is, I think, clearly the reason why Georgian houses were so often placed close to the road in order to give more space and seclusion to the gardens lying behind them.

After seclusion comes usefulness. Gardens were not made merely for pleasure, but to provide the home with necessities and delicacies elsewhere unattainable. Fruit growing was a fine art. The bakehouse, brewhouse, game larder, fishpond, dovecot, herb garden, walled fruit garden, orchard, quincuna, and stillroom were necessities, and not merely evolved out of playful fancy. Then there is, I think, no doubt that the fishpond or tank owed its origin in mediæval Catholic England to the demand for fish. The old-fashioned herb garden too must not be forgotten. The culture and curving of "simples" was formerly part of a lady's education, and gardens were ofttimes renowned for this feature alone. There was also the necessity for good, dry paths and terraces, for it was in the garden that exercise was largely taken, roads being few and bad. The garden was therefore an integral part of the home—indeed, an absolute necessity—for, if the household was not self-supporting, it could barely exist. Thus garden and house grew up and were designed together, for each was the complement of the other.

The next question is—Do these principles still hold good; are the same necessities still in existence; can we, after making all due allowance for the lapse of centuries and rapid growth of modern requirements, still say that the same factors should form the basis of good garden design in this twentieth century, and, if so, how is the architect thereby affected? A little consideration will, I think, show that in reality almost all the old conditions should apply at the present time.

First, seclusion. The greater number of houses, and the greater chances of being overlooked by near neighbours, serve to make strongly defined boundaries, which will act as screens, even more imperative than ever, and thus we have ample excuse for "high-walled gardens green and old," hedges thick and trim, and well-designed trellis as bounding lines.

Of the usefulness and necessity of a garden the need is still the same, though perhaps at first sight not so apparent because the reasons are more psychological than materialistic. Fruit and vegetables can probably be bought from the greengrocer as cheaply as they can be produced in most private gardens, but the demand for them is greater than ever. Jam and pickle factories have done away with the absolute necessity for home growing, but I think everyone will agree that home-made jams are far superior. I am sure that few people realize how much can be done and how much pleasure obtained from even a limited number of well-cared-for fruit trees, and what is more beautiful than an apple or pear orchard either in early summer or autumn? Then, too, there are many trees such as mulberry, quince, medlar, cherry plum, filbert, which, while full of delight to the eye, are useful as well. These planted with discernment will give pleasure to generations. Without going quite as far as Voltaire's "Candide" and saying, "Let us cultivate our garden, for that comprises the whole duty of man," I am certain that if nowadays gardening, not merely flower gardening, but honest fruit and vegetable growing, with the accompanying culinary knowledge, was better understood and followed we should hear less of broken nerves and jaded energies. There is no recreation more healthful than gardening, and health is the ground plan of all that is worth having in life. Then, too, there is its educational influence, especially upon children; and there is no better way of teaching scientific truths and imparting a true system of observation of nature than by means of the well-ordered garden. Of the joy of the "pleasure garden" there can be no doubt, and, surely, we should be able to appreciate this part of the garden, and derive moral and physical good from it as much as our ancestors. . . . . The house and garden still require each other to make the home one perfect whole. Each must fit in with the other, and each must be in most cases subject to some special circumstance of site and locality.

Who, then, is so fitted to bring this about as the man who designs the house? He must have a hand in the laying out of the garden, or full advantage of the site may be lost, and so the chance of welding together house and garden through some happy accident of nature may be missed for ever. How can we convince our clients that one mind should control the two? The end can only be achieved by taking our client (or more often his wife) with us. If he is a careful man, or anxious of expense, it may be well to approach the garden from the materialistic point of view. Point out the desirability of determining where surplus earth may be removed at one hauling, and thus save labour and form your broad lines all in once. The making of paths from old material may be suggested, or the position of the carriage drive if the house is to have one. If by some such means the ice can be broken then, perhaps the rest may be plain sailing. If the man or woman has any real love of the garden, out it will come, and the resulting garden should express not so much your individuality, but the owner's directed by a trained mind, but still expressing, and that, too, decidedly, the owner's particular quips and cranks. . . . Before, however, the architect can scheme anything, there are certain facts he must know. First comes the question of garden labour. He must ascertain exactly what amount of labour will be kept, for upon this hangs in reality the whole scheme. It is suicidal to design a garden which requires the time of four men to keep it in proper order if only two are to be kept. It will always look untidy, and the owner will never feel satisfied, and will blame the designer, who assumed a responsibility without due knowledge.

The chief charm of a real garden is, I think, shown in the care which is taken of it. If the turf verges are shaggy and ill-kept the charm of line is gone, and the feeling of love and care which should be induced will be wanting. I know a garden, and I say garden advisedly, which is only some 16 ft. by 20 ft., and yet year in and year out it is the pride of a village, and that solely by reason of the love and care bestowed on it by its cottage owner. I know also gardens which are gardens in name only because they are too ambitious for the staff. . . . Some excellent practical advice on the subject of garden labour is given in Mr. Mawson's "Art and Craft of Garden Making," but the best way of arriving at a reasonable judgment is to carry in our minds some garden or gardens we know well and the number of men who are employed, comparing the results obtained with the size of the garden and using our knowledge with designing.

Having discussed preliminaries and discovered the trend of our client's garden mind—if, fortunately, he has one—the choice of the actual position and aspect of the house will largely depend upon the result arrived at. For instance, we might choose a level site for a lawn to avoid expense in moving earth, and the position thus chosen might affect the house considerably. It is often far better to take old meadow turf in hand rather than to sow afresh, especially where time is an object, for turfing and sowing can only be done at certain seasons, viz., spring and autumn, and then the the result depends largely upon weather, which is chance. Nothing so makes or mars the appearance of a garden as good or bad turf. Generally some characteristic of the country side or natural feature on site, which may lend itself to our gain, can be seized upon, and may influence or modify both house and garden, proving how essential it is that the architect should have the necessary knowledge to turn the accidental peculiarities of the site to the best advantage.

It must not be forgotten that in almost all gardens there is a chance and opportunity—indeed, a necessity—for some architectural features which it is essential the architect should design or control. It is here that the modern garden designer and horticulturist necessarily fails. He has not had, in most cases, the requisite architectural training, and not having designed the house, he perforce loses that sympathetic link in detail which the architect would impart. The old gardens were full of architecture, and such buildings as tool-houses, potting-sheds, root-houses, stone steps and balustrades, summer-houses, dove-cots, seats, and thoughtful trellis work were features in them. Such are required still, and, if used with restraint, will help to add human interest. But the necessity for them should be the keynote. Do not let us introduce them simply to make "features." If a seat is desired it will work its way into the design, and by its presence, add to the garden's beauty. The sun-dial, though apparently no longer a necessity (in these Grimthorpian days), is most fascinating, and, if used rightly, will set our thoughts working and lend just that touch of romance which is needful to both eye and memory. Above all, let us keep garden architecture simple both in form and feeling. It is not what we put in so much as what is left out that sets the seal on the perfect garden. The old formal garden had almost degenerated into grotesqueness by the eighteenth century from over-elaboration. To be a garden designer, the architect must have a knowledge of garden craft. He must know and love the materials he has to deign with—namely, the flowers, grass, trees, and herbs, and must be fully alive to the fact that a garden is a living, growing thing.

So much has been said lately about gardens from the practical point of view that I will only refer briefly to this aspect of the subject.

First, then, soils and drainage. Obviously the latter depends upon the former, and until considerable practice has given us knowledge, I would suggest that we first of all ascertain what is the local custom as to treating the soil, and how much or how little drainage it requires. Mr. Mawson says that "unprepared soil is the cause of almost all garden failures." Secondly, we must discover what grows well in the neighbourhood, for it is no use designing and planting trees or boundaries which will only need replanting after some years.

Thirdly, botanical or horticultural knowledge. Without going very deeply into this question we must know something of the times and seasons at which the flowers we propose to use will make their richest appearance. We need not know the best way to make them grow, but may presume that will be done for us. Observation and a garden notebook will teach us much. Well-made, dry paths and walks are a practical necessity, for wheeling soon cuts them up unless the foundations have been well prepared. Fruit and flower gardens must have both sun and shelter, or plants will not grow, and early and late frosts will do a deal of unnecessary damage. The house-drainage scheme must not be overlooked, and advantage should be taken of all manurial products.

In effect, then, the burden of my paper is this: House and garden must be treated together, and be the product of one mind—the architect's. He may scheme his garden as he pleases so long as it is subordinated to the house, and he always keeps before him its fundamental uses and objects—seclusion, usefulness, and pleasure. . . .

* Summary of a paper by H. P. G. Maule, read before the Discussion Section of the British Architectural Association.

NOTES.

On March 12th last Judge Somerville, of the United States Board of General Appraisers, ruled in favor of the protest of Mr. Bohm, an architect of Indianapolis, against the assessment of 20 per cent. on certain drawings made by him in Europe.

A competition has been instituted to secure suitable plans for the buildings of the Carnegie Technical Schools, Pittsburg, Pa. Five leading architectural firms have been invited to submit designs in a limited competition, and will each be paid $1,000. The competition is open to all architects whom the Committee may invite. Five additional prizes of $1,000 each will be paid to the five architects whose designs stand highest in merit. Architects desiring to enter this competition are requested to provide the committee with information as to their professional work upon blanks to be had from Director Arthur A. Hamerschlag, 313 Sixth avenue, Pittsburg, Pa.

PLUMBERS' WORK, PAST AND PRESENT.*

By W. H. Allen,
Late Teacher of Plumbing, Cardiff Technical Schools.

It would certainly be interesting to consider, in the light of present-day practice, the methods adopted by the plumbers of old in the centuries that are gone, but in that case the subject of my paper should have been that of "Plumbers' Work, Ancient and Modern"; so for the purpose of setting out with a clear understanding of my intentions, I propose to confine my comparisons to those of my own experience and recollections during the past thirty years.

And to prevent misconceptions of any remarks that I may hereatter make, let it be understood that I propose dealing with the subject entirely from a plumber's point of view. By that I mean that, while I fully recognize and appreciate the many improvements that have taken place during the above period from a public health point of view, I look forward with pleasure to the discussion that will follow upon this proposition, viz. :—That the progress made has been prejudicial to the plumber as a craftsman, and that the whole of the benefits from such progress and improvements have been to the benefit of the public.

From a purely trade point of view, then, are these improvements to be regretted? In reply I would say, with all the emphasis possible, certainly not! If these improvements have made life any easier, or have added anything to the sum total of human happiness, we as plumbers have no right to regret that we as a trade have suffered; and considering how small a proportion we are of the people, we must stand aside, and if necessary "go to the wall," if by doing so we can in any way make those of our day and generation the better for it.

This gives rise to another thought :—Have we as a trade been fully alive to the fact that, owing to the more modern methods of manufacture, &c., the work to be done by the operative has been constantly reduced? Have we done all that we might have done to add other branches to our trade when we saw so many slipping away from us? My own opinion is that in this respect we have been somewhat lax, and we have only ourselves to blame for the position we now find ourselves in.

But I must not dwell upon this further, or my alloted time will be taken up before I approach the subject proper. I must therefore leave it with you for further elucidation in discussion.

ROOF WORK.

The first call upon the plumber in the construction of a building is when the roof is ready, and here we find a marked difference. Much lighter lead is used, and far less of it. We find valley tiles, hip and ridge tiles used in place of lead, and zinc has become a keen competitor with lead for valleys, gutters, bays and dormers. Parapet gutters, lead hips and ridges are practically a thing of the past—not that this can be attributable to the fault of the plumber or architect, but to the present-day demand for cheaply-built premises, also to the construction of concrete and asphalt flat roofs, which has removed the necessity for lead flats.

The old way of lining eaves gutters (made of wood) with lead, and rain-water down pipes made of lead, has been entirely superseded by the extensive use of cast-iron. Lead rain water heads, and the covering of finials, gargoyles, and other ornamental finishes, has been reduced to a minimum by the use of those made of cast-iron or terra-cotta. So that it will be seen that the quantity of plumbers' work in connection with the external work of a building has been very much reduced in the period I have mentioned.

WATER SUPPLY.

The question of how the building should be supplied with water is the next consideration.

To-day all we have to ask is "Where is the main?" and then to run our pipes from the prescribed point to the various fittings we have to supply. But it was not always so. In the days before the advent of constant supplies at a sufficiently high pressure, many things had to be taken into consideration, such as the method of supply, whether from some higher point by gravitation or from the more frequent source of wells. Was it to be an ordinary pmp or a lift and force pump? Was it to be a deep well pump, or was it to be supplied from rain-water storage tanks? Then the sizes and positions of the storage tanks, the rising main to them, the supply pipes from them—all this meant a great deal of work for the plumber, and in this connection the plumbers have been great losers, and the public have benefited materially.

When one realizes how difficult it is to-day to find work in a plumber's shop when work is quiet, one is forcibly reminded of the days that are gone. One can remember, when there was nothing else to go on with, the old story of, "Make up a few pumps," the burning up of the barrels, the fitting-in of copper chambers, making the spouts and the casting of the taper box-pieces; and how careful we were told to be when, as boys, we had to hold the iron bar in the sand mould, ready to swish it around, smartly and regularly, so as to get the box-pieces of an even thickness; and how, if it was successfully accomplished, our mate took all the praise, but when it turned out of uneven thickness, how the boys had to bear all the blame!

And, again, who does not remember, when the taper box-pieces were superseded by the spindle valve, how a quietness as still as death had to reign in the workshop while the valve was being fixed level in the tail pipe ready for wiping? The making of cup-leathers, the leathering of boxes, the casting and leathering of clacks—to say nothing of the sundry journeys to the blacksmith's to see if the iron work was ready—all this has gone never to return.

The young plumber of to-day can have no conception of the amount of work the plumber had to do in connection with deep well pumps, both of the long barrel pattern and the short barrel which are fixed in the wells; the fitting of the suction and rising main pipes, the fixing and repairing of the pumping gear, sometimes involving the use of many intricate cranks and cog wheels. This was always attended to by the plumbers. He was the mechanical engineer of these jobs, and the existence of such arrangements added considerably to the plumbers' work.

The change in internal fittings has been very marked also. Instead of the well-made H.P. taps that we have now, we then had to deal with plug taps made of the

*A paper read before the South Wales and Monmouthshire District Council for the National Registration of Plumbers.

diaphragm pattern; taps poor in design, often defective, and the plumber was called in to remedy the defects.

Baths were but rarely met with in the old days, owing to the difficulty nf getting the necessary water; and this, with the hot water services, perhaps is the only compensation plumbers have for the substitution of constant service supplies against that of pump supplied houses.

The old form of supplying baths in the best houses was that of the triple valve arrangement, by which means the hot and cold water was supplied through the waist outlet; and while condemning it from a sanitary point of view, it was the means of giving a lot of work to plumbers.

The present-day method of fitting up lavatories is far preferable to that of the old, which involved much more work in fixing the supply valves against the wall, with a breeching pipe and supply to arm of basin, and its putty or red lead joint. This is yet another instance showing how the work has been lessened.

Sinks and troughs, which were formerly lined with lead, have been replaced with copper, or more frequently with those of glazed fireclay.

Supply cisterns, which were formerly of lead, are now made of galvanized iron, or in some cases of copper and but very rarely of lead.

Who would have believed in the old days, when we were busily at work striking out and wiping up service boxes and fitting in the old bells or poppet valves in water-closet cisterns, that the day was coming when such work would be as extinct as the Dodo? Yet it has all gone. The lining of the cistero, the making of the service boxes and wiping them in meant more work for the plumber than the whole job of fitting up a closet does at the present time. To-day we have the cistern delivered at our shop doors, complete and ready for fixing, and either made of cast-iron or earthenware.

When the plumbers had to make their own soil pipes, bends and traps they could always depend upon having work to do in the shop, but no employer would to-day dream of letting his men make a soil pipe with its soldered seams, and the introduction of hydraulic presses has entirely superseded the making of such articles by hand labor. All this has tended to reduce the available amount of work to a minimum.

A marked change for the better has taken place respecting the methods of wiping. Well do I remember the first lesson given to the plumber's boy, viz., that of cooling the plumbing iron, the getting ready of the quench hook, the cooling of the handle so far up, the seing that the iron was not burnt, the filing off of the scales, and above all the correct way of handing the iron to your mate, as it had a nasty habit of falling back and touching you up. And after the great event of wiping was over, the care taken in picking up the bits of solder—for solder seemed more valuable then than it does to the boys of to-day.

Before treating with the question of water-closets I would like to refer to the making of the rightly-condemned old-fashioned D-trap, but we did not know of its bad character then.

One can remember the old set of patterns hung upon the wall of the shop, religiously preserved from generation to generation; the wiping in of the dip pipe, and the great care exercised in seeing that it was not too far down or too high up. These considerations involved a deal of care and thought on the part of the plumbers of those days.

But whatever fault we may find with the D-trap, we must all acknowledge that it was a nice job to be making them, and it was with regret we parted with them, and have only our recollections of them left.

The old pan closet has been anathematized over and over again, and I have not one good word to say of it, only that it was the means of providing work constantly for plumbers. In well ordered houses it was a standing job to take them out, and clean, black and re-tin the copper pan once every 12 months. So here again the public have benfitted at the expense of the trade.

The valve closet, and one maker's in particular, was a source of much work. How many will remember the patience required in dealing with the intricate regulators, and resisting the desire to drop one's "big hammer" through the pan! But these are going the way of the old pan closet, and are practically replaced by the more modern closets in earthenware.

The work of fitting up wire bells was formerly done by plumbers, and was a very important branch of the trade. To give you an idea of the comparative cost of the old-fashioned wire bells as against electric bells I will tell you of a case that has recently come before me.

An architect is about to build a gentleman's residence a few miles out of town, and he specifies that the bells are to be of the old-fashioned kind, with wires and cranks, &c. The fittings are to be supplied by a certain firm who make a specialty of this class of work, and upon asking them for a quotation for the material required, they very courteously informed me that they had already quoted several people for the work, and their price was £60. Now if this job was done with electric bells, many would be glad to get it at from £15 to £20.

I only refer to this as an illustration of the decline in this class of work, because it is the labour item that would be more reduced than that of material.

But this is not the worst part of it. When electric bells were first introduced, we, as a trade, failed to see "the sign of the times," and neglected to grasp this branch of the trade as we should have done.

I am speaking generally because I am aware that there are some few exceptions to this general statement; but nevertheless the majority of us failed to grasp it, and so we can add bellhanging to the "what might have beens." Not that it is too late even now to recover ourselves. I am sure that if we once realize the necessity for it, we will take full advantage, and receive our share, of a branch of the trade that is rapidly falling out of our hands and into the hands of electrical fitters.

I am perhaps laboring this question of bellhanging, but it is because I have experienced on the part of the plumbers a strongly rooted objection to have anything at all to do with electric bell work.

In recent years there has been a very serious decline in the gasfitting branch of the trade, so far as it concerns the plumbing trade generally, and it is due to two distinct causes—1st, that of the introduction of electric light; and 2nd, to that of the competition of gas companies.

Taking the latter first, what do we find? We find that, owing to the fact that the companies supply stoves on the hire system, this branch of the work has practically ceased to exist so far as the trade is concerned,

because no one would buy a stove out and out when they can hire so cheaply and so frequently exchange them. It is a matter of finance to the company. It pays them to let the stoves out at a nominal charge for the sake of the extra gas consumed. And now we know that the company will fit up a house with pipes and fittings free of charge, with a penny-in-the-slot meter—not from philanthropic motives, but because it means a greater consumption of gas. All these things, small though they may be in themselves, tend to reduce the work available for plumbers.

Now as to the lighting of premises electrically. Here again we missed our opportunity as a trade, and again I must qualify this general statement. There were a few (but even those were somewhat late in doing so) who endeavored to commandeer this branch, which was at the commencement legitimately ours, whatever it may be now. At that time the electrical fitter was not. He had to be made. There were none at that time, and we as plumbers should have mastered this work, and so prevented it from slipping out of our hands. Weether this branch can be recovered I an very doubtful, because I think the electrical specialists are too firmly established ; but I do not wish to discourage the attempt to do so that is being made by several members of the trade, and I feel assured that the result depends upon individual energy and enterprise. Whether we ought to stand aside and permit the electrician to monopolize the whole of this work is a matter of opinion that can be freely expressed by you in discussion.

Hot water work, or, as generally set out on the shop windows, "Heating Engineers." Why has this branch become specialized as it has of recent years? I know this is the day of specialization, but I do feel that we as a trade have ourselves to blame for some of it.

Perhaps it is hardly fair to put it that way either, in this case ; because we never heard of hot water engineers until the ironmongers got hold of the trade. In the old days the plumber had to do it all, and he was always ready to tackle any job that presented itself. But when the ironmongers were masters of the plumbers they employed, they had no respect for the success of the trade or the maintenance of its position. They employed anyone they liked to do the work, and so a distinct class of men has been created, now designated as "hot-water fitters," and to the detriment of the plumber.

Another important factor, too, must be considered, and that is the building of greenhouses and conservatories has developed into a special business. Firms undertake the whole of the work, inclusive of the heating work. So this branch has ceased to exist as an admitted branch of the plumber's trade.

It is assuredly worth our while to make every effort to get as much of this work as we can, and in passing permit me to suggest that we might, as a body of men deeply interested, spend more time together than we do in considering what means can be best adopted to regain our lost position, or, to put it another way, to secure as our legitimate work what should in all fairness belong to the plumber.

I think I have cited sufficient to prove a great diminution in the work of the plumber, notwithstanding the fact that the number engaged at the trade doubles itself every five or six years. And after the instances I have pointed out, which serve to show a great reduction in the available amount of work, you will ask how we have managed to live through it all?

Well, on the other side of the count we have to put the greatly increased number of houses fitted up with conveniences that would not have been done if the water supply was as it used to be. And again you must remember that we have been building new houses at a very rapid rate, and this new work has helped us. But we know it cannot always be so. Building operations have been severely checked of late years, and will probably be so for some time to come ; and it is when we have reached the limit of our building resources that the pinch will be felt so far as it relates to the work of the plumber.

It therefore behoves us to carefully examine our position, and to ask ourselves if we are doing all we can to establish an equilibrium, by taking up other work in the same ratio as we have lost it and are losing it. We can never return to the old order of things. The making of pumps and D-traps has gone, and can be buried as useless ; and in these days of progressive sanitation we would not, if we could, have them back again.

The advantages of a constant supply of pure wholesome water to a community cannot be represented by a money value. It is one of the essentials of life, and a pleasing feature of the healthy advancement of our national and municipal progress. The abolition of unsanitary fittings and the substitution of those of a sanitary kind are also amongst the blessings of an enlightened age. We must therefore "wake up," and by facing our difficulties we shall know best how to meet them.

Permit me in conclusion to justify myself for the position I have taken up in including what may be called the outside branch of the trade. I have included them because each of these branches have been deemed to be a part of the trade, both during my apprenticeship and in my after life ; and because they are so considered even to-day in the majority of the shops in the provinces.

In large centres like London, Glasgow, and other places, it may be that lead layers stick to that particular branch ; and inside or sanitary work might be done by another set of men. And so with the branches of gasfitting, bellhanging and heating. But in this district I know from experience how very much one branch depends upon another, and while the specialist of our trade might be inclined to smile and think I have made "a mountain out a mole-hill," I feel assured that many of you who are able to see the matter through my spectacles will consider that the peculiar conditions of the trade justify me in so including them.

PERSONAL.

Mr. J. A. L. Waddell, of Kansas City, Mo., has had the degree of Doctor of Laws conferred on him by the Missouri State University. Mr. Waddell is a Canadian.

Mr. Herbert B. Rugh, formerly of the firm of Guilbert & Rugh, architects, Racine, Wis., has just opened an office at No. 367 Main street, Winnipeg, and would be pleased to receive catalogues and samples from the trade.

A large number of members of the Institute of Civil Engineers of Great Britain are to visit the United States and the St. Louis Exhibition in October as the guests of the American Society of Civil Engineers. It is said to be their intention to visit Montreal on September 20th and 21st, Ottawa on the 22nd, and subsequently Quebec, Toronto and Niagara Falls.

CAUSES OF A NEW YORK BUILDING FAILURE.

Mr. H. de B. Parsons, the expert appointed by the New York City authorities to report upon the causes of the recent collapse while under construction of the Hotel Darlington, a steel frame structure, states that primary causes for the failure of the structure were faulty design and carelessness and neglect in the erection of the members. The actual cause of the collapse was the lack of lateral support for the columns, which permitted them to act as 'long columns'— that, the ratio of length to least radius of gyration exceeded the limit of safety.

Mr. Parsons further states: "Each floor was lettered and the columns varied in size on the same floor, a specimen schedule being as follows :"

Floors.	Letter.	Column. Side. Inches.	Thickness. Inch.	Height. Ft. In.
Basement	A	9	1	10 6
Ground	B	9	¾	14 6
2	C	8	¾	10 10
3	D	8	¾	10 10
4	E	7	¾	10 10
5	F	7	¾	10 10
6	G	6	¾	10 10
7	H	6	¾	10 10
8	J	6	¾	10 10
9	K	6	¾	10 10
10	L	6	¾	10 10
11	M	6	¾	10 10
12	N	6	¾	10 10
Hight to under side of roof beams				144 2

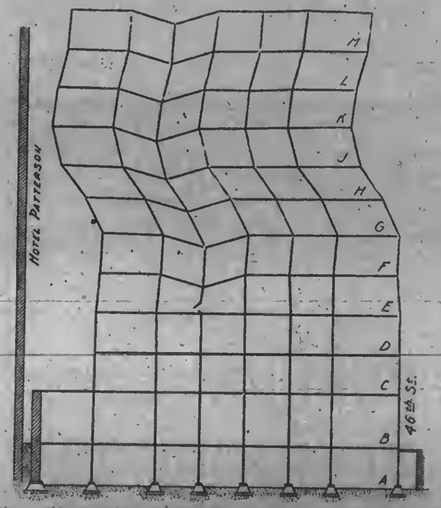

Fig 1.—Side Elevation of the Steel Frame, showing in slightly exaggerated form the failure of the column on the fourth floor, resulting in the collapse of the structure above it, which crashed through the lower portion of the building. The break occurring just back of the centre of the floor, the structure had a natural tendency to fall toward its centre, the greater amount of metal in the front, however, pushing the rear portion backward.

"Practically the building was pin connected. The bolts fastening the girders and beams against the column lugs were of smaller diameter than the holes, so that the columns received little or no lateral support. The column lengths were bolted together at the top and bottom, and acted as continuous columns. All loads were eccentrically supported on the side brackets. In consequence, the columns were too long to carry the superimposed weight and buckled. One column situated at or near the 'center of fall' broke. The upper part of this column being deprived of its support fell, and pulled with it the floor members bolted to it. Each of these floor members pulled over the adjacent columns to which the other ends were attached, and these columns having no lateral support broke at the lower flange, as the pull had a lever arm of about 10 feet, or the length of the column. This action and reaction of the stresses affected only the structure above the level of the original fracture. In fall, the mass off material from above crashed down and broke that part of the structure below the level of the original fracture.

"The exterior columns did not break of as low down as the interior columns, because the mass fell away and

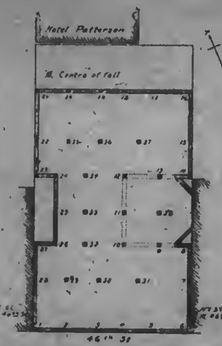

Fig. 2.—Floor Plan, showing the location of the cast iron columns according to their proper numbers, and indicating the "centre of fall" slightly to the rear and left of the centre of the building.

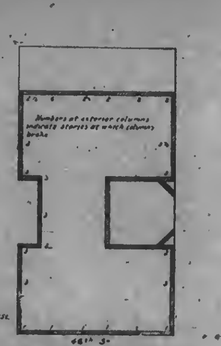

Fig. 3.—Floor Plan, showing the location of the cast iron columns in the outer walls, and indicating the stories at which these columns broke. The inside columns were practically all broken off at their bases.

did not crush them as it did the interior ones. The uniformity in hight at which the exterior columns broke strongly indicates that the primary fracture occurred at or about the level of the fouth floor.

"As proof that the top fell into and toward the 'center of fall' before the lower part of the structure collapsed, columns G 11 and K 11 were taken out of the debris near the 'center of fall' and from beneath other members, which originalily were connected at points lower down in the building. Near the same spot column D 36 was found standing in a nearly upright position. Of these columns, the first was broken at the centre and the other two at the flanges. Furthermore, as more of the structure was south of the 'centre of fall' than north of it, the northern, or rear, portion was forced outward against the Hotel Paterson."

NOTES.

The British Consul General at Berlin reports that the efforts to form a combination of the cement manufacturers throughout Germany for the purpose of improving the conditions of the cement manufacturing industry, have thus far not succeeded. Manufacturers in certain districts have got together, and they are now striving to bring in the South German and other North German groups.

In the course of the recent excavations at Pompeii there has been discovered and placed in the Museo Borbonico at Naples a bronze wire rope an inch in circumference and some 15 ft. long. It consists of three strands laid spirally together, each strand being made up of fifteen wires twisted together, and its construction does not, therefore, differ greatly from that of wire ropes made to-day. Pompeii was destroyed in A.D. 79; but how long wire ropes had then been known it is impossible to tell, though, judging by the knowledge shown in the construction, it may be safely concluded that they had been known for a considerable time. The uses to which these ropes were put are not definitely known ; but further excavations may possibly shed some light on the subject.

because no one would buy a stove out and out when they can hire so cheaply and so frequently exchange them. It is a matter of finance to the company. It pays them to let the stoves out at a nominal charge for the sake of the extra gas consumed. And now we know that the company will fit up a house with pipes and fittings free of charge, with a penny-in-the-slot meter—not from philanthropic motives, but because it means a greater consumption of gas. All these things, small though they may be in themselves, tend to reduce the work available for plumbers.

Now as to the lighting of premises electrically. Here again we missed our opportunity as a trade, and again I must qualify this general statement. There were a few (but even those were somewhat late in doing so) who endeavored to commandeer this branch, which was at the commencement legitimately ours, whatever it may be now. At that time the electrical fitter was not. He had to be made. There were none at that time, and we as plumbers should have mastered this work, and so prevented it from slipping out of our hands. Weether this branch can be recovered I an very doubtful, because I think the electrical specialists are too firmly established; but I do not wish to discourage the attempt to do so that is being made by several members of the trade, and I feel assured that the result depends upon individual energy and enterprise. Whether we ought to stand aside and permit the electrician to monopolize the whole of this work is a matter of opinion that can be freely expressed by you in discussion.

Hot water work, or, as generally set out on the shop windows, "Heating Engineers." Why has this branch become specialized as it has of recent years? I know this is the day of specialization, but I do feel that we as a trade have ourselves to blame for some of it.

Perhaps it is hardly fair to put it that way either, in this case; because we never heard of hot water engineers until the ironmongers got hold of the trade. In the old days the plumber had to do it all, and he was always ready to tackle any job that presented itself. But when the ironmongers were masters of the plumbers they employed, they had no respect for the success of the trade or the maintenance of its position. They employed anyone they liked to do the work, and so a distinct class of men has been created, now designated as "hot-water fitters," and to the detriment of the plumber.

Another important factor, too, must be considered, and that is the building of greenhouses and conservatories has developed into a special business. Firms undertake the whole of the work, inclusive of the heating work. So this branch has ceased to exist as an admitted branch of the plumber's trade.

It is assuredly worth our while to make every effort to get as much of this work as we can, and in passing permit me to suggest that we might, as a body of men deeply interested, spend more time together than we do in considering what means can be best adopted to regain our lost position, or, to put it another way, to secure as our legitimate work what should in all fairness belong to the plumber.

I think I have cited sufficient to prove a great diminution in the work of the plumber, notwithstanding the fact that the number engaged at the trade doubles itself every five or six years. And after the instances I have pointed out, which serve to show a great reduction in the available amount of work, you will ask how we have managed to live through it all?

Well, on the other side of the count we have to put the greatly increased number of houses fitted up with conveniences that would not have been done if the water supply was as it used to be. And again you must remember that we have been building new houses at a very rapid rate, and this new work has helped us. But we know it cannot always be so. Building operations have been severely checked of late years, and will probably be so for some time to come; and it is when we have reached the limit of our building resources that the pinch will be felt so far as it relates to the work of the plumber.

It therefore behoves us to carefully examine our position, and to ask ourselves if we are doing all we can to establish an equilibrium, by taking up other work in the same ratio as we have lost it and are losing it. We can never return to the old order of things. The making of pumps and D-traps has gone, and can be buried as useless; and in these days of progressive sanitation we would not, if we could, have them back again.

The advantages of a constant supply of pure wholesome water to a community cannot be represented by a money value. It is one of the essentials of life, and a pleasing feature of the healthy advancement of our national and municipal progress. The abolition of unsanitary fittings and the substitution of those of a sanitary kind are also amongst the blessings of an enlightened age. We must therefore "wake up," and by facing our difficulties we shall know best how to meet them.

Permit me in conclusion to justify myself for the position I have taken up in including what may be called the outside branch of the trade. I have included them because each of these branches have been deemed to be a part of the trade, both during my apprenticeship and in my after life; and because they are so considered even to-day in the majority of the shops in the provinces.

NOTES.

The report of the building inspector of Vancouver shows that during the eight months since October 1st, 1903, there have been erected in that city 568 dwellings and over 100 buildings for business purposes.

As mentioned in a previous number it had been decided to remove the Eiffel Tower in Paris, but this decision has now been changed, and the Tower is to remain and to be adapted for use as a wireless telegraph station. The civil engineers of France presented a request that the Tower be not taken down, and the Minister of War conceived the idea of using it as a Military Station for receiving and sending wireless telegraph dispatches. The inventor, Mr. Eiffel, being anxious that the structure should remain, offered to pay all the expenses incurred in adapting it to its new purpose.

Canadian firms in a position to handle successfully the goods of any of the above British exporters, should communicate with them direct, mentioning the CANADIAN ARCHITECT AND BUILDER.

PLASTERERS' PRICES.

The Plasterers' Section of the Toronto Builders' Exchange have recently adopted and issued in printed form the following schedule of prices and rules of measurement, based on the existing prices of material and labor:

RULES OF MEASUREMENT. — Rendering, lathing, plastering, deafening and limewhiting measured by superficial yard; all measurements taken full and 5 per cent. allowed from total for openings.

For circular work allow double measurement.

For domes and groins allow three measurements.

Cornices, mouldings, beams, etc., measured by square feet. Circular work measured double.

Coves, angles, beads, metal angles, jambs and enriched members measured per foot run.

In case of deductions from contracted work, an allowance to be made to contractor of 15 per cent. for loss of profit. This rule only applies where total amount of work done is less than amount contracted for.

Dubbing out to be charged where plaster exceeds three-quarters of one inch in thickness.

Allowance for hoisting charges to be made for all work over two stories in height.

Heat, fuel and attendance, where not specified, to be charged for.

The Canadian Bridge Co., Limited

Walkerville, Ontario

MANUFACTURERS OF

STEEL BUILDINGS, ROOF TRUSSES

Price 50 cents

Copies sent postpaid on receipt of price

Canadian Contractors' Hand-Book and Estimator.

The third edition of the Canadian Contractor's Hand Book is now on sale. The book has been revised and enlarged to upwards of two hundred pags, and the title changed to the Canadian Contractor's Hand-Book nnd Estimator, considerable matter bearing on the cost of performing various kinds of work having been added.

The price of the third edition, mailed free, is $1.00 to subscribers of the CANADIAN ARCHITECT AND BUILDER, and $1.50 to non-subscribers. Order from the publishers,

The C. H. Mortimer Publishing Co. of Toronto, Limited
Confederation Life Bldg, Toronto.
Alliance Building, Montreal.
310 McIntyre Block, Winnipeg.

Where color is mixed with finishing coat of plaster an additional charge is to be made for same.

PRICE LIST.—Metal lathing nailed to wood furring per square yard, 36c.

Metal for junctions, beams, coves, arches, columns, etc., to wood furring per square foot, 5c. (but not less than 5c. per foot run.)

Metal lath formed to wood cornice brackets, etc., per square foot, 10c. ; (but not less than 10c. per foot run.)

Metal lath tied to metal furring, on plain surfaces, per square yard, 40c.

Metal furring and lathing to metal brackets for cornices, domes, groins, etc., subject to special prices.

Wood lathing, plain surface, 16 inch centers, 12c.
Wood lathing, plain surface, 12 inch centers, 13c.
Wood lathing, one inch wide, additional, 2c.
Rendering, before strapping, 8c.
Rendering, after strapping, 10c.
Deafening, 1½ in. thick, lime mortar, 20c.
One coat of mortar on lath, 25c.
Two coat on lath, hard white finish, 30c.
Two coat on lath, stucco finish, jointing additional, 37c.
Three coat, hard white finish, 37c.

" on metal lath, additional, 30c.
Keene's cement work, portland backing on brick walls, $1.25.
Same on metal lathing, $1.50.

Moulded cornices, one cent (1c.) per inch in girth, but not less than 18c. per foot run, material not to exceed 1½ in. in any place. All mitres over four in a room to count as one foot each by the girth.

Coves, per foot, 10c.
Coves, metal, per foot, 15c.
Angle beads, per foot, 10c.
Metal angles, per foot, 12c.
Window or door jambs, 3 in. deep and under, 10c.
Centre flowers, ordinary stock, 24 in. diameter and under, put up, each, $2.00.
Enriched members, not over 2 in., ordinary stock, per foot run, 10c.
Larger or special centre flowers or enrichments governed by character and selection.
All work modelled to be charged extra.

PRICES OF TIME AND MATERIALS.—Plasterers to be charged per hour, 53c.
Lathers, to be charged per hour, 48c.
Laborers, " " 37c.
Overtime to be charged time and one half.
Metal lath, per yard, 30c.
Lath, per thousand, $4.25.
" per hundred, 50c.
Lath nails, per pound, 6c.
Sand, per yard, delivered, $1.50.
" per barrel, 30c.
Mortar—Per load, double team, $5.00; delivered, $6.00.
" single " 3.00; " 3.50.
"½ " " 1.50; " 2.00.
"¼ " " 75c; " 1.25.

Timber Specifications

Great changes have taken place during the last decade in quality and varieties of timber for construction purposes. White pine, which was the standard material twenty years ago, is year by year becoming scarcer and higher in price. This has caused the introduction and compelled the use of other kinds of timber, such as British Columbia fir and cedar, hemlock, southern pine, etc. For many purposes these substitutes are quite as good as the high grade white pine so largely used in the past. The Engineering Record states that architects and engineers have neglected to keep themselves fully informed regarding the changed conditions, and are still using forms of specifiations employed when white pine was the universal material. If this be the fact, our contemporary is quite right in its contention that timber specifications should be revised and adapted to the conditions now existing.

Toronto Building By-Law.

The Toronto City Council have adopted the new building by-law drafted by the City Architect, Mr. McCallum. Objection was taken by the local architects to a number of provisions in the by-law, and the Council appointed a committee on which the architects were represented to consider it in detail. The City Architect was unfortunately taken ill before the committee had got far advanced with its work, and the Council not deeming it wise to delay action, adopted the by-law. It is understood, however, that the Council have requested the architects to formulate their objections and have promised to give due consideration to any suggested amendments to the law. Action in this direction will be taken by the architects as soon as the rush consequent upon an unusually busy building season shall have subsided. While the by-law appears to require amendment in some particulars, it places the regulation of buildings on a basis altogether more satisfactory than formerly, and praise is due both the City Architect and the Council for prompt action.

Vaults.

The recent great fires in Toronto, Baltimore and elsewhere have called attention to methods of vault construction in buildings, and the extent to which vaults may be depended on to fulfil their purpose of protecting valuable documents deposited in them. Investigation of this question following the Baltimore fire showed the contents of twenty two bank and trust company vaults to be uninjured. The walls of these vaults were built up solidly of hard brick laid in cement 16 inches thick without iron supports, and were supported on brick foundations extending to the foundations of the buildings. Mercantile vaults, which owing to their greater number, are quite as important

as those already mentioned, were in many cases found to be faulty, and the users suffered heavy loss. The principal causes of failure were found to lie in cheaply constructed doors, lack of proper connection between doors and masonry, and vault doors and walls having been so tied to the walls of the building that when the latter fell the vaults went with them. This is a subject of such importance that it should receive the most careful attention at the hands of architects and building owners.

City Schools. Fortunately the price of land in Canadian cities has not yet reached the point where serious restriction is placed on the size of school sites and playgrounds. In New York no space is provided for playgrounds outside the area of the school buildings. Whatever provision is made for recreation is as a rule contained in the basement of the building. An exception to this rule has been made in one or two instances where a room for play has been provided on the roof, by carrying up the exterior walls, stretching wire netting over the entire top and making the flat surface of the roof waterproof, or converting the entire top storey into a playroom opening on to the roof. In the former case, receptacles containing steam pipes are placed below the roof level for melting the snow which might lodge upon the roof. Under such conditions as these school children cannot be expected to attain their highest physical or mental development. We in Canada should assure the welfare of future generations of children by making ample provision now in our cities for school and public playgrounds.

Decrease of Trade Disputes in England. It is gratifying to learn from a recently published Government report that for some years past in England disputes between employers and employees have been steadily decreasing. The average number of such disputes during the five years 1893 to 1897, was 816, and for the five years 1898-1902, 632. The number last year was only 387, affecting about one per cent. of the industrial population, loss of time amounting to less than one-fourth of a day per head. The majority of disputes arose over the question of wages. About one fifth were due to demands for the recognition of the unions. A large number of the disputes of last year were settled by the parties interested and through the agency of the Boards of Conciliation and Arbitration. This is a hopeful sign of the times, indicating the use in the future of more reasonable methods of adjusting differences of this character and consequently more harmonious and satisfactory relationships between employers and employees, such as formerly existed. It is to be hoped that Canada will not be found to be behind the motherland in this important reform.

Canadian Building We regret to note that the Canadian Building at the St. Louis Exhibition is as conspicuously common place and uninteresting as were those at previous exhibitions of the kind. It belongs to the jig saw class of architecture and as such is perhaps representative of country architecture in Canada twenty years ago, but certainly does not in any degree whatever represent either Canada or Canadian architecture of the present day. The occasion warranted the erection of a creditable building, the design for which the government might have secured by competition among Canadian architects. It is both humiliating and annoying that the development of our country and architecture should be so misrepresented before the world. Surely the Dominion Government, which boasts of having a surplus this year of more than $16,000,000 could afford to expend a few thousand dollars on the construction of a well designed building which would compare favorably with those of other countries, and of which Canadians would have no cause to feel ashamed. If as a people we are too poor to do this, let us not advertise our poverty by putting up any more poverty-stricken buildings at International Exhibitions.

New Union Depot for Toronto With commendable promptness the railway authorities and representatives of the City of Toronto presented to the Railway Commission at Ottawa their arguments as to the terms which should govern the transfer to the railways of a site for a new union station on the south side of Front street. With equal promptness the Railway Commission fixed the terms which have been declared to be satisfactory to all parties concerned. There remains therefore no obstacle in the way of the immediate carrying out of the enterprise, the early completion of which will materially advantage both the railway and the city. The present terminal facilities are not sufficiently modern or convenient in arrangement and are entirely inadequate even for the rapidly growing passenger and freight traffic of the G.T.R. and C.P.R. The desired entrance into the city of the Canadian Northern Railway brought the project for improved accommodation to the point where action upon it could no longer be deferred. The decision arrived at should ensure the construction of an imposing building in the heart of the burned district and the immediate removal of the unsightly debris now covering the site, which might otherwise have remained for months or years. It will no doubt also tend to encourage the early construction of a good class of buildings on the surrounding property and greatly improve the approach to the city whether by rail or water. The importance of securing the best possible plan for so important a structure is obvious. The best result would probably be attained by a limited competition among a number of leading Canadian architects. This would bring to bear upon the problem the best thought of a number of trained and experienced men, from whose combined efforts a thoroughly satisfactory solution might be expected. For the success of this plan two things are necessary (1) the appointment of competent arbitrators in whom the competitors would place confidence to draw up equitable conditions to govern the competition and judge the plans; and (2) a sufficient sum in premiums to compensate for the time and expense involved in the elaboration of so important a scheme, together with the assurance that the author of the design awarded first place would be given charge of the work. While the majority of Canadian architects are unusually busy at the present time, the season is now well advanced, and no doubt many would be found willing to enter a competition which would offer them opportunity to distinguish themselves, provided the conditions were fair and the prizes attractive.

WREN'S CHURCHES.

(SECOND ARTICLE)

In a previous article an example was given of one of Wren's plainest plans, which is nevertheless a pleasing and interesting church. It would be going too far to say that the plainest plans are the most impressive, but the greatness of the impression compared with the simplicity of the means is striking—and instructive.

There are only three further developments in the members of Wren's church plans, apart, that is to say, from the shape of the plan which was varied in several ways. He added a sacrarium or sanctuary, a single aisle, and a double aisle. It might be added, as additional variations, that the aisles were sometimes galleried and sometimes not.

Of the sacrarium plan, All Hallows, Lombard street, is a good example (Fig. 1). Wren went no further

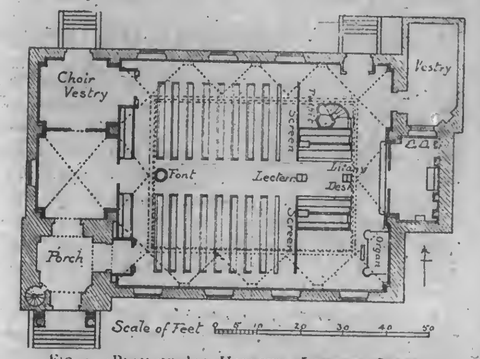

FIG. 1.—PLAN OF ALL HALLOWS, LOMBARD STREET.

than this in the development of the East end. There was no thought, in his day, of placing the choir at the east; the communion table alone had to be provided for, and this recess, which is 20 feet wide (or 18 feet between the pilasters at the angles), is handsome without being unmanageably large. The great difficulty connected with its insertion lies in the junction of ceilings; for the sanctuary should not be a hole in the east wall, but should rise to the fullheight of the church and its ceiling should run with the main ceiling.

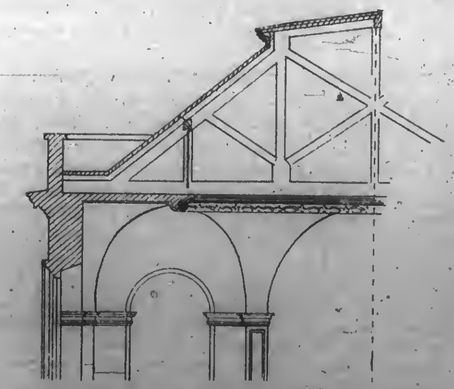

FIG. 2.—SECTION OF CEILING OF ALL HALLOWS, LOMBARD STREET.

Wren's way of managing this was to have a main ceiling with a large cove and to penetrate the cove for the sanctuary. The ceiling, which is shown by dotted lines on the plan, has a cove 9′ 6″ deep and 8′ 0″ in projection, terminating in a large roll and cornice (Fig. 2) which runs round and makes a central panel 32′ 0″ x 44′ 0″—a field for decoration in secular work of this period, but never so treated in these churches. The windows in the north and south walls of the church have round heads, springing like the cove from the top line of the cornice; so the cove is penetrated for the windows, which are so spaced as to break up the cove into continuous penetrations, and these are continued over the blank spaces on the east and west ends, which have round-headed recesses to supply the motive. The central penetration of the east end forms the inlet of the sacrarium ceiling. This penetration is about 5 feet wider than the others. The 5 feet of increase is accomplished by an adjustment of the angle of penetration, which must produce a flatter curve, but the eye cannot discover its difference from those on each side of it.

The extent of opening that can be spanned in this way is limited by the size within which a ceiling cove must be kept; so that the expedient does not solve the difficulty of reducing the width of a single span body for a choir (which would be wide as compared with a sanctuary) while keeping continuity of roof. It is, however, a question whether this difficulty is not better accepted than solved, for the choir is better of the same width as the body than narrowed to make a sort of cave in the east wall of the body.

It is hard to say, in view of the 156 feet width of the single span of the new Roman Catholic Cathedral of Westminster, that the width of the body of a church can ever be too wide for the choir, if there is length in proportion; but, though the choir needed for a church 350 feet long will be no more than suitably housed in a choir 156 feet wide, should the church be 156 feet wide and compelled to be about the same in length, it is time, on account of both practical and proportional suitability, to take to columns.

Wren, as a churchbuilder, is usually thought of in connection with his largest churches, with their double colonnade and galleries; but he used columns in many different ways, to reduce his churches to a convenient form that could be economically roofed. There is not much evidence of any gradual development of his types one from another, but the dates of completion of the churches show that he favoured certain types more at one time than at another; and in the last ten years of his practice there are four little churches of one kind which, though their idea appeared earlier, may be taken, by their frequent appearance at that time, to represent ripe judgment. This type is the one-aisled plan. The difference between one aisle and two aisles is greater than the difference of an aisle. In a one-aisled church the appearance may be said to be that of a body with an aisle appended. When there are two aisles the composition is made by the aisles; it is an aisled church; the distinction between body and aisles becomes a mere matter of nomenclature for convenience of reference to locality; there is no separation in the mind. What makes this difference between one aisle and two aisles is of course the solid wall on one side of the one-aisled church. This limitation is associated in the mind with the other side also, so that the body is felt to be the church and the aisle an appendage.

When first seen in plan, such a church may appear to have an uncomfortable lack of symmetry, and perhaps it is not for nothing that this type is confined to

churches of small size. On a large scale, the more dignified symmetrical plan with double aisles is necessary, no doubt, if there are aisles at all; but for a church of this size and even larger—St. Lawrence Jewry is nearly 50 feet wide and over 80 feet long—a one-aisled plan is much to be preferred to a duo decimo copy of a grand church with double aisles. The variety given in a one-aisled church by the two sides, with responding composition, but different appearance, is a source of more actual interest than is given by double aisles.

If the seating space of two aisles is desired a gallery may be inserted. The philosophy of the gallery, apart from considerations of expense, is that when the congregation is small it need not be used; and thus scattering, which has a bad moral effect, may (in these days of free seats) be prevented. When the congregation increases, or if there is a special occasion, the gallery comes in as additional seating space. In this way St. Margaret Pattens—which appeared to be comfortably populated by a week-day congregation which counted as 62—is said to be seated for 500—has held 600 sitting persons, counted by the verger; and is thought to be capable of giving standing room to 100

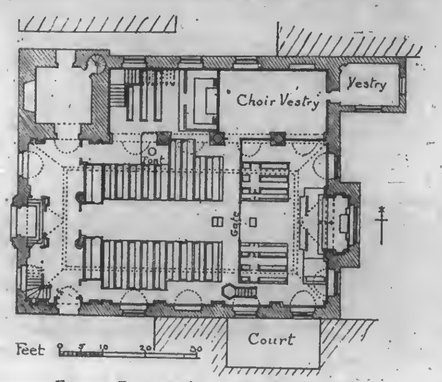

FIG. 3.—PLAN OF ST. MARGARET PATTENS.

more. This elasticity is due in great measure to the handsome allowance of space for passages, which is common to all the city churches and contributes so much to their dignity. At first this feature seems anything but encouraging, but as a means to effect it is on the whole cheap. It is the additional space, over what is necessary, that makes the difference; and, if the additional space only is taken into account, its cost will not amount to much to set against the cost of columns and arcading. Moreover, whereas dignity is to be got by superfluous space without arcading, it is not to be got by arcading without superfluous space. The lesson of what can be got by superfluous space only is a lesson of the necessity of superfluous space under all circumstances. Superfluous space is an aesthetic necessity, but it has this advantage over other aesthetic necessities that it adds at a pinch to the seating accommodation.

In the case of St. Margaret Pattens, the gallery front is an additional interest and the portion which is enclosed for a choir vestry also encloses satisfactorily the choir within solid walls.

There is a low screen or fence, of panelled and carved oak, enclosing the front of the choir, with an open-work wrought iron gate across the passage.

The ceiling is similar to that of All Hallows, Lombard street, in plan, but smaller in scale. There is a cove, penetrated for a portion of its height for a circular clearstory window over each intercolumn, and penetrated its whole height for the sanctuary opening; which latter is then finished by an arch and a barrel vault.

The organ is at the west, in a gallery over the vestibule. In so small a church this works perfectly and is in fact an improvement, for the organist at work is no gain to the east end. In a large church the evidence of experience is, on the whole, against separating in this manner the organ and the choir; but the evidence is not so strong as might be expected. It is only in the seats towards the east of the church that there is any doubt about the blending of sound. At the western end of the church it is perfect.

W. A. LANGTON.

BY-PRODUCTS IN THE PORTLAND CEMENT INDUSTRY.*

In the course of the investigations conducted by Dr. W. Hillebrand at the request of the Committee on Uniform Methods of Analysis of Materials for the Portland Cement industry, he found that when a raw mixture which contained 0.69% of potash and 0.22% soda was ignited in a platinum crucible for one hour over an ordinary blast lamp, the resulting cement contained but 0.07% of potash and 0.09% of soda. The alkalies had been nearly completely volatilized and the potash more completely so than the soda.

It at once became of interest to determine whether the same thing took place in the industrial production of Portland cement clinker. It was found that from a raw mixture made from marl and clay which contained the percentages of alkalies mentioned above and which should in consequence contain 1.26% of potash when burned (if none of it was volatilized) since the loss on burning was 37.50%, 0.65% potash was carried off in the flue gases at the temperature of the rotary kiln. An investigation of the flue dust proved that the alkalies were carried further than the point where this material is deposited and it is apparent that by conducting the gases through a horizontal chamber where the temperature could be reduced to a point low enough to permit of the deposit of the potash, this could be collected, perhaps, aided by a spray of water or steam.

The importance of this discovery is apparent if a calculation is made of the actual weight of potash which is produced and lost this way in a cement plant turning out 4,000 bbls. a day, or 700 tons of material. Six-tenths of one per cent. of this would mean 4.2 tons of potash which now goes to waste, but which could be readily collected and have a value of a least $12 per ton (that of kainite with 12% potash) and with a probable value of $45 per ton that of commercial emeriate used for fertilizing purposes. In the latter form over 4.2 tons of potash would be the equivalent of 6.6 tons of emeriate, so that allowing the excessive sum of $50 per day for the expense of the process and interest charges, the profit from a single plant of the size mentioned would be between $100 and $200 per day. It would seem that the development of the process would be of commercial interest. In conclusion it may be said that Dr. Hillebrand has an application pending for a patent covering it.

*Paper read at the 7th Annual Meeting American Society for Testing Materials, By CLIFFORD RICHARDSON, Long Island City, N.Y.

SOME REMARKS ON ORNAMENT.

By FRED. T. HODGSON.

There has perhaps been no other art which has made such radical improvements within so short a period as that of ornamentation, and this has been accomplished in the face of great difficulties, and by very peculiar methods.

The artistic and studious decorative architect is forced to combat that constant and ever-present belief entertained by women, that in the decoration of their homes their own individual taste should prevail, notwithstanding the fact that their ideas of color and harmony are necessarily crude and undeveloped. So also there are numerous charlatans in all the building trades, who persuade their customers that a decorative architect is unnecessary and a mere fanatical encumbrance. Still, ornamentation has steadily improved, until it can now be said that there is a decided change for the better in the various methods of treatment, which change, however, has not to any appreciable extent affected the ideas of the public generally.

Many sensible men who have some instinctive idea of the "eternal fitness" of things, not only employ an architect to design and superintend the building of their homes; but they engage them to design the furniture and general decoration. This is as it should be, for an architect—if worthy of the name—is better fitted to design or choose fitting furniture and proper colors for decoration, after designing the main structure, than any other person or number of persons possibly can be.

It is within the memory of many now living that after the teaching of the late unfortunate Oscar Wilde, a change seemed to take place from the old established forms of ornament to new and improved methods of treatment; and a study of the ideas of Mr. Wilde will disclose the fact that there was "a method in his madness", since, by his many peculiarities, the minds of people were attracted to that which otherwise would have passed unnoticed.

There is, however, a sad lack of originality in ornament, since its choice is of far more importacce than designers as a rule are able to discover. For example, a stencil or wall-paper, is to be designed, The natural impulse of the average designer is to rush to "Owen Jones's Grammer of Ornament" for an instance of the school decided upon; but, in accordance with all reason, this is just that which should be avoided, since the text books will soon be exhausted, and finally, when the designer has run the gamut of ornament by copy, he will discover how, for lack of thoughtful study, his work is without originality. If our designer be a man like Mr. Louis F. Day, he will invent an ornament of no particular period or school, but a combination of the motives of as many as afford material for a design complete in itself, uniform, and of one part—not, as is too often the case, consisting of details and actual parts of a number of schools assembled or thrown together and called an original design.

It is the study of the motives and principles of the various schools of ornament, and not their mere imitation which is required to produce original designs.

It may not seem amiss or pretentious to suggest a few rules, giving illustrations showing their applicability, for observance in ornamentation.

First—Ornament is not necessarily a decoration applied to an object independent of its construction, but should be a part or whole of its construction. This rule is aimed at the prevalent ideas which at this time are nearly obsolete. Formerly it seemed to be the intent of the cabinet maker, for instance, to hide obvious necessities and in order so to do, ill adapted relief carvings were glued on to the surface, and useless knobs and handles were attached, all natural openings being hidden by mouldings and fillets.

It is now the rule to avoid attaching to the object unnecessarily ornament, and to embody in the article itself the ornamentation.

Second—The ornamentation should not in any way interfere with the utility or object of the article. For instance, it is almost impossible to find two paper knives exactly alike, and yet it is equally impossible to find more than one in a dozen which has not been over ornamented. The ordinary paper knife is very likely to have a handle covered with spurs, or rough portions, making it painful to grasp, as in many cases turned, or carved, to such an unreasonable extent as that it is too frail for use, the original object of the knife being sacrificed for ornament. As example of graceful ornament, and well worth consideration as an illustration of its utility, are some of the iron registers in churches or other public buildings, however, admirably adapted for the purpose; perfectly flat and even on the surface, the open space so arranged as to allow the air to rise evenly, and the ornament so disposed as to sustain great weight.

Third—The material should be treated naturally.

That is, if wood, it should be treated as wood, and not twisted and painted as only iron should be, and, if metal, it should not be moulded to represent a log of wood, or wood carving, as it often is.

Fourth—The ornament chosen should be suitable and appropriate.

A bunch of wild flowers painted on a miniature shovel is not appropriate; decorated clothes pins to fasten napkins are hardly beautiful; an old shoe, dried and gilded, used as a receptacle for flowers is not suitable, and in all these cases it is thrusting into view objects which are not pleasantly associated with the drawing room or table.

Fifth—The object should never be made to represent that which it is not.

A door or wainscoting may appear to be walnut, mahogany or oak, but a chip at a corner or a joint, or even a casual inspection, discloses the truth that that which was originally a cheap wood has been covered with a coat of staining and the skulking grainer has traced the markings of a more pretentious wood thereon.

Few arts have been more radically modified by the introduction of machinery than the art of building. The stone mason holds his own againt the innovator more stubbornly than the carpenter; but almost entire dwellings, above the foundations, are now manufactured in factories and then delivered on the ground ready to be placed in position. The men who set them up are still called carpenters, the wrong word of the old title "carpenter and joiner" having been retained. They would be better classified were they called joiner, or they might be called finishers in carpentry; but they are certainly not in any true sense carpenters. The real carpenter has become a machine and though this machine may be able to prepare only the manufactured material for frame buildings, it is equally true that all the interior fittings, whatever the material, of brick stone, or

marble buildings, are now in a great measure factory made, and delivered ready to be placed upon the walls or whereever they may be needed.

Machine and stuff, so far as architecture is concerned, cannot be said to be a gain in the direction of art, though, from an economic point of view it has its advantages. It has enabled us to build well with a greatly less expenditure of money than building operations, would cost were we dependent upon hand labor alone, and it is also the cause of a great deal of building that would never take place bnt for its co operation. It is quite certain that much of the building to be witnessed in our great cities is due to the existence of wood manufacturing firms, and were it not for their fransactions building operations would have to be greatly curtailed. These advantages, however, are gained at the expense of true art.

MONTREAL LETTER.

No. V.

Some fairly extensive additions are now being made to the Law Courts and this leads the Gargoyle to make certain reflections with regard to this building as a whole. The characters of individuals are expressed in their dress and conversation and may be readily discerned in the things they make, or do or get made and done for them or even in the objects they select and purchase to surround them in their daily life. Just so the character of the citizens must be discernible in their public buildings. Architects or builders of whatever degree of skill or accomplishment are simply taking the ideas of their clients in verbal instructions and rendering them back to them in stone, lime, wood, or whatever material may be ordained by those who order. It will be just therefore to examine the courts which a city has built in which to have justice administered and to judge of the city itself thereby. Let Montreal then in this matter pass under the architect's cross examination.

This building is of no mean dimensions showing that the citizens had a sense of the importance to them of Justice, who, in a city which invites traders and workers from all ends of the earth to the continual friction incident to busy commerce and great material enterprises, must not be huddled in a corner to do as well as straightened circumstances will allow her, but must have ample space to exercise her rule. Rightly also the Law Courts stand quite in the busy haunts of men, and yet free from actual contact; for the hands of Justice must be clear of the strife she is to judge. Though in the lower part of the city the Courts with their neighbour the City Hall crown a small ridge sufficient to make them conspicuous in the city itself and also from all more distant points of vantage.

Approaching from Craig Street, it is with pleasure that one comes into the spaciousness of the Champ de Mars and raises the eye towards the two large buildings which dominate the open space from its farther side. The Parade Ground itself has a painfully arid look, but the young trees which demurely dot its borders give promise of a pleasanter future. The manner in which this ground is terraced high above Craig street affords a noble base for the two chief buildings of the city.

All this is very satisfactory and makes one eager to make acquaintance with the features of this home of Justice so wisely and advantageously placed. The best view is obtainable from Craig street, and the expectant glance meets with a rebuff that sends it staggering in the direction of the City Hall to catch if possible some gleam of hope, but only to recoil once more to find perhaps a little rest and comfort in the simple honest faces of those buildings which from St. Gabriel street have reviewed the manœuvring troops for a hundred years.

These buildings actually have their backs turned towards this fine space! Why, yes, they must have backs somewhere you know; and Notre Dame street and a superior class of business have their claims on the other side. But why such aggressive backs anywhere? What has Craig Street done? Is it Justice that should wear good cloth in front and shoddy on her back and turn it uncomoprmisingly upon the poor? If through lack of gold her dress cannot all be of finest stuff at least why not of one good web throughout? Last week we spoke of the Bank of Montreal, and taking a cast back along Craig street one may there see a stately, stalwart, honest back enough, not overlaid with elaborate drapings but having only the simple necessities of the case wrought into an organic expression it rises straight and simple from footpath to cornice a 'living' wall of stone.

This matter of the back of a building is one in which the Mooteregians have a particularly rooted misconception. There is little doubt that this arises from the fact that in Montreal excellent stone is obtainable at no very great cost but brick is more readily obtainable at a less cost. Hence it has become a habit, and a very irritating one it is, to make buildings with a stone front and brick sides and back. I suppose people who like houses of this sort must be the class which wears one character on Sunday and another the rest of the week. The only presentable one is for Sunday wear and meets with much acceptance from those like minded. The stone front to the brick villa is of a similar value. It is not a virtue but it is a homage paid to a virtue too expensive or too troublesome to be actually maintained. There are certainly better ways of meeting the case. Some models of a very sensible and legitimate method exist among the works of Mr. Norman Shaw, as for example the buildings of Scotland Yard in London and the offices of the White Star Line in Liverpool. Both these grand buildings stand on bases of hewn stone or granite and the upper stories are constructed of brick with the occasional introduction of bands or members of stone in such a manner as to make of this interchange of materials a decorative motif of distinct architectural value. The nobler material thus keeps helping out its humbler fellow all along, and together they form a unity and not a motley assemblage of elevations.

But we have wandered from the Law Courts. Let us return and try to feel thankful that the back was not built of brick. Let us suppose that the apparent one sidedness of Justice is not occasioned so much by the poverty of Craig street as by the well known distaste of Lower Canada for an aggressive militarism here only to plainly represented by a drilling ground and a drill hall. Likely enough Justice is only very properly refusing to countenance dragooning operations.

The original law court building has been one of quite considerable quiet dignity and force of character, its front in quiet retirement behind a little grove of trees has still a pleasant expression of dignified calm. This structure has consisted essentially of a basement or ground storey of chamfer jointed masonry surmounted by two stories unified in point of design by large Ionic columns extending through both. The main entablature has then formed a crowning member to the whole building, which, though broad and simple, is not without an agreeable variety of features. Unfortunately this has not been considered sufficient for the needs of an increasing city. On the top has therefore been added another storey in the form of a classical "attic," built indeed of stone but crowned with a cornice and balustrade, both apparently of sheet iron. In the centre of all rises a kind of saloon deck in a number of stages surmounted by a dome. All this portion is executed in . . . . ; well, some Toronto man might read this, so I don't like to mention what the top of our Law Courts is made of, but the owners are doing their best for it and have just given it a nice new coat of paint which makes it look as like stone as can be expected—that is to say, very unlike it indeed.

Now Montreal who is to blame for this? Will you put the blame on your architect? The most inferior architect I ever knew would have preferred to use stone, and the more inferior he might be the more reasons would he have had for using stone—the superior man could only have one. Moreover the hand that is displayed in this additional work shows a greater sense of refinement than that which controlled the original building, which though honest simple, and robust, inclines to harshness. Surely the citizens that have had the seat of Justice in their midst thus stuck with cheap trappings were wanting in respect to Justice and to themselves.

Let us next have a look at the works at present in progress. It would be expecting too much that these should entirely redeem the situation, tacked on as they are in an odd corner facing a narrow street on the opposite side of which are some old buildings between St. James street and Notre Dame street. For the sake of the Law Courts it would be well if this block of buildings could be removed. The new buildings though standing well in view along the eastern and finer part of St. James street, do not occupy any definite relation to that thoroughfare. We have sufficient faith in the architectural soundness of the original building to wish that an effort had been made to bear it out in the new. Yet in spite of all these disadvantages it must be admitted that the treatment of the new building has a boldness and vigour of its own. The work being still incomplete, it is too early to criticise it as a whole, but the strong handling of the ground storey with bellied courses of approximately semi-circular section and the strong simplicity of the two upper stories make one anticipate some excellent work.

It is surely to be regretted that looking at this building from Craig street it appears to attach the block of buildings which form the Law Courts to the general mass of the city on this side thus destroying the appearance of isolation which is so valuable to an important building. In addition to this, this side has again been treated in a most summary way as a thing of no account. If the tenants on Craig street are at all sensitive they must feel more than ever like pariahs from whom respectable citizens turn their faces. The moldings of the front are taken round for a few feet and then returned on themselves and everything is bare to baldness. Again if it be asked—Is not the architect to blame? One must reply: Is an architect likely to want to do things so, or is it not more likely that they should be forced upon him? This sort of thing is the evidence of want of self respect on the part of the citizens.

The moral of all this is that an architect has got to educate his clients so that they may give him proper instructions, and if he be an architect of civic buildings he has to educate the officials with whom he deals so that they may train the general public to give him proper instructions. To prepare themselves for such tasks as these architects must get up very early in the morning. So the Gargoyle turned in for the night.

GARGOYLE II.

PORT ARTHUR AND FORT WILLIAM.

(Notes by a Travelling Correspondent.)

The past year has been marked by the rapid progress made by the twin cities of Port Arthur and Fort William, both of which have developed into great shipping ports for the vast crops of wheat produced in our great west. Every citizen of both cities has a right to feel justly proud of the steady advancement made and which is still continuing. Fort William alone has expended no less a sum than $248,000 in business blocks and residences, an increase over that of the preceding year of $100,000, while the population and assessment have increased over 25 per cent. The Canadian Pacific Railway Company has completed at this point one of the best coal handling plants on the continent of America, and has also erected and is now operating elevators "D" and "E," and a modern machine shop capable of overhauling four large locomotives per month, besides other works of slightly less importance. The Imperial Oil Company's works here for supplying the Canadian market west of this point still continue to grow, and during the year they have handled 2,000,000 gallons of refined oil, besides 5,000 barrels of lubricating oils and 4,000 cases of other products. The John McKellar Memorial Hospital which was opened June, 1903, has supplied a long felt need, while so great have been the demands made upon it that it is almost safe-evident that an addition will soon be necessary.

In Port Arthur over two hundred and fifty dwelling houses have been erected at a cost of $250,000, and some $175,000 has been spent in the erection of stores, offices, warehouses, etc. The Canadian Northern Elevator Company has expended over one million dollars for increased elevator capacity and docks and the King Elevator Company some $250,000 in connection with its storage annex.

In lumber circles the Northern Land and Lumber Company, a party of Wisconsin capitalists, have erected a very fine planing mill and are handling large stocks of white and yellow pine.

At present building operations are not nearly so brisk in either cities as they have been during the past two years as the construction of the projected large elevators has not yet begun and also a large amount of money has become tied up in speculative real estate. Mr. M. B. Aylesworth, one of the leading architects of Port Arthur, is now busily engaged on several important buildings in both cities, including the city hall of Fort William, a stone and brick office building in Port Arthur for Councillor T. N. Andrews, a large residence for Mr. James Meek, the Provincial Court Clerk, a store and dwelling for D. M. Davidson, residences for H. G. Greenland, of the Bazaar, and John Ritchie school inspector for the district, and a new stone Methodist church, while he is now busily engaged drawing out plans for a giant skating, curling and hockey rink. The city hall at Fort William has been in progress for nearly one year, but it is not expected it will be ready for occupation before June of 1905. However, work has been pushed rapidly along on the Auditorium wing, which will be ready for the opening entertainments in the course of a month or so. The proceeds of these opening entertainments are to be devoted to the John McKellar Hospital fund. The estimated cost at completion of the City Hall will be $70,000.

Besides the work undertaken by Mr. Aylesworth in Fort William there are three good sized business blocks, a four roomed school house and a large number of good residences in course of construction. The Canadian Pacific Railway Company, in place of the burnt elevator are erecting a large working house for the series of elevators. They have recently completed a large power house for supplying electric light to their yards and power for pumping, etc. A large brickyard has also been added to the industries of the town, this making the fourth; all are operating to their fullest capacity.

At Port Arthur there is a possibility of a smelter being erected to handle the rich iron ore deposits of Loon Lake, which lie twenty miles to the north of the city. A charter has already been applied for by the company to enable them to build a short line railway to Thunder Bay.

Architects of Ontario and the States will be much interested to learn that the long disused stone quarries of Vert Island in Nepigon Bay are about to be worked again. They have been idle for the past twenty years having been in the first place opened up to supply the stone for the erection of the famous wholesale house of Marshall Field & Co. on 5th ave., Chicago. The Sawyers Bay green stone quarries have lately been operated to supply the recent demands of the twin cities.

CANADIAN MASTER PAINTERS' AND DECORATORS' ASSOCIATION.

The first annual convention of this new organization was held at the Windsor Hotel, Montreal, during the last week in July, the president, Mr. L. Z. Mathieu, presiding.

Papers were read and discussed as follows: "Advantages of Membership in the Master Painters' Association," by Stewart N. Hughes, Toronto; "Our City Fathers, Their Relation to, or With Labor Organizations," by A. M. McKenzie, Hamilton; "Varnish, its Uses, Methods of Manufacture and Adulteration," by A. T. Blackwell, Toronto; "Necessity for Trade or Technical Schools," by W. E. Wall, Cambridge, Mass.; "The Purifying of our Establishments from the Evils of Unionism," by J. N. Arcand, Montreal; "Competition in the Painting Business," by Jas. Phinnemore, Toronto; "The Apprenticeship Question," by W. T. Castle, Montreal; and "Reminiscences and Comparisons in the Painting Business During the Last Half Century," by John Murphy, Montreal.

The officers elect for the ensuing year are: President, J. N. Arcand; Vice-president, A. M. McKenzie; secretary, Stewart N. Hughes; committee, Messrs. O'Hearn, Brooke, Johnston, Morley and Stamp. Messrs. L. Z. Mathieu, S. N. Hughes and G. S. Faircloth were appointed delegates to the international convention at Milwaukee.

The social features included visits to local manufactories and an evening reception in the hotel parlors.

Exhibits of painters and decorators materials were made by Messrs. Berry Bros., the Canada Paint Co., Ramsay & Co., Sherwin-Williams Co., Watson, Foster & Co., Colin McArthur & Co., and Stauntons, Limited.

The next convention will be held at Hamilton.

NORTHWEST NOTES

Branch Office of THE CANADIAN ARCHITECT AND BUILDER,
310 McIntyre Block, WINNIPEG, August 12, 1904.

Building operations have been somewbat hindered during the past month, the holding of the Dominion Exhibition in Winnipeg since last issue having naturally turned all thoughts in that direction, and for the last few weeks the usual amount of work has not been done. There are still a great number of building permits being granted, but chiefly for small houses, the demand for which is still very active. The Winnipeg Street Railway Company are on the eve of starting the erection of some additional sheds and works in the Southern suburb of the City, the result being that property in the vicinity has been materially advanced in price. Work is just about to begin on the new Opera House, a project which has been in contemplation for some time. Excavators, too; have just commenced work on the property of the T. Eaton Company of Toronto, preparatory to the erection of the large departmental store they are proposing to open in this city. The Bell Telephone Company are also contemplating the erection of a new factory alongside of their present one, which will about double their present warehouse space.

CEMENT BLOCKS FOR BUILDING.

An exceedingly interesting feature of the exhibits in the Dominion Exhibition, and one which came at a particularly opportune moment, was that of the various appliances for making cement blocks. In our last issue we pointed out the great difficulty which has been experienced in Winnipeg in obtaining materials for building. Brickmaking has been pushed forward with great energy, but with little apparent effect in satisfying the demand. The stone industries are unable to keep work under way and many buildings which would have otherwise been completed are now not likely to be finished before next season opens. To the interested observer, therefore, these exhibits must have been instructive. In the States it seems that cement is fast gaining in favour as material for building. The evolution of machinery in its application to the cement industry, places on the market a "block" which appears to be commending itself wherever the subject has been given due consideration. As a fire and weather resister cement stands well to the front, and as regards appearance and durability, it is quite capable of holding its own. The subject is one, therefore, to which architects and builders are giving a good deal of attention. Its cost is materially less than stone and its appearance almost equal. As compared with brick, the labour in laying cement blocks is less costly and can be executed by less experienced workmen, which gives it a set-off against the apparently larger original cost, many claiming that in result it works out less costly than a brick building.

Foremost of these exhibits was that of the North-west Pressed Stone Company, who were shewing a "block" for which they hold a special patent not only as regards the block itself, but also the machinery for its manufacture. A great feature of this block is that it has a double air space and it is impossible to pierce a wall built with these blocks without encountering an air space. The company also carries a complete outfit of machinery to work in conjunction with the block-making machine, so that an outfit can be installed to work with the minimum amount of labour and equal to 400 to 500 blocks per day.

Another power cement block making machine was that shewn by Messrs. Gutteridge & McConnell, of Hamiota, Man. This machine was capable of 90 strokes per minute and the actual time taken to produce a perfect block was three quarters of a minute. With this machine it is possible to produce 600 blocks per day. A special feature of this machine is a device by means of which a block can be made with a colored face of cement some two inches thick, with the remainder of the block in natural colour.

The National Cement Block Machine Co., of Toronto, were shewing a machine with a special non-corrosive metal plate, which certainly made a block scarcely discernible from a block of stone. This machine, however, was not adapted for power; by hand labour the output would be some 150 blocks per day.

The Cement Building Block Co., Ltd., of Winnipeg, had also on exhibition a sample of their work in the form of a wall with details, such as corners, doorways and windows. It was stated that the machine exhibited, worked by hand, produced some 120 blocks per day.

The Canada Petrified Brick & Stone Co., Ltd., had on show a sample of their products, erected to show the usual mode of construction, both for their special make of brick and also for their hollow cement block. Their chimney blocks attracted special notice as making an exceptionally neat finish. This company have a secret in the manufacture of their goods whereby the cement and sand are joined together, and get extremely hard by age.

These exhibits are of special interest at the present time when the building question is one of great importance and the hindrance to progress is mainly that of not getting sufficient material.

DECORATION AT THE EXHIBITION.

There was nothing large or particularly new in this feature of the Exhibition. To those who are aware of the immense strides made in the Eastern Provinces in this direction, it would appear that a good opportunity has been lost in this ommission. The ordinary class house in Winnipeg is usually disposed of in an unfurnished state as regards internal decoration and often remains so in the hands of the occupant for a great while so that there is ample room for stimulating these lines. The Metallic Roofing Co., of Toronto, the western agent for whom is Mr. T. Black, 130 Bannatyne ave., Winnipeg, made an excellent display. Their stand was a large and prominent one, and extended right across the centre of the building, the walls being arranged in sections, each shewing a different decorative treatment in artistic colors. This company also showed embossed metal shingles and sidings. Their designs of roofing tiles known as "Spanish Diamond" and "Gothic" attracted much attention and comment.

The Winnipeg Ceiling and Roofing Co., of Winnipeg, also exhibited a fine ceiling arrangement of Imperial design, mounted in a massive gilt frame, which shewed to advantage. This company, we understand, are the only actual producers of this line of goods in Winnipeg.

Mr. E. S. Holston, of 937 Logan ave., Winnipeg, had on show a selection of high grade front doors made in special patterns, and of fine quality and finish. This firm aim to keep on the market goods of the highest grade and to supply only wholesalers.

The Winnipeg Paint and Glass Co., Limited, had an attractive exhibit, prominent in which were three samples of cut and ornamental glass. They also exhibited an attractive array of glass doors, built and turned newels and internal fittings generally. An attraction at this stand was their exhibit of model cottages shown in the interests of Ramseys' paints, and which presented a very gay appearance.

The Winnipeg Mantel Company had on show a fine range of mantels, grates and tilings.

The Canada Plate & Window Glass Company, of Toronto, were exhibitors of fireplaces and fireplace fittings. They shewed an unique range of these goods, arranged with good effect and also had on show samples of their ornamental and plate glass.

STOVES AND FURNACE EXHIBITS.

The industry more largely represented than any other, and which commended almost universal interest, was that of the stoves and furnaces. Probably the largest and finest exhibit in this department was hat of the Gurney Foundry Company, who besides having an exceptionally fine position, had also laid it out in a most attractive manner, with a full line of their cooking and heating stoves, furnaces and radiators, decorated in pleasing colors.

The Record Foundry & Machine Co., of Montreal, Moncton, Toronto and Winnipeg, also showed a fine range of stoves and ranges, and although they have recently increased their capacity, are still finding it difficult to meet the demands of their trade. This company showed a specially constructed combined furnace adapted for either small houses or large buildings, and which commended itself as particularly adapted to this district.

The Lennox Manufacturing Company also showed a furnace, the main features of which were a steel dome, particularly sensitive as a heat holder, and an interchangeable fire pot; it was claimed that the consumption of fuel in these stoves was considerably minimized. The Western agents are Merrick Anderson & Co., Winnipeg.

The Christie Bros., Limited, 238 King street, Winnipeg, agents for the Canada Heating & Ventilating Co., Owen Sound, had on view a range of cooking stoves of unique construction. These stoves are so arranged that the heat encircles the oven twice, making it a perfect baker and cooker. They also showed the Empire King heating furnace, for either coal or wood, and with some special features covered by patent rights for the whole Dominion.

The Moffatt Stove Co., of Weston Ontario, who have offices and warehouse at 214 Princess street, exhibited a complete range of stoves and heaters.

The Doherty Mfg. Co., of Ontario, also showed their well known Decarbon steel stoves and heaters.

The Western Foundry Co., of Wingham, Ont., the western agent for whom is Mr. W. S. Black, 404 McIntyre Block, Winnipeg, had on exhibition samples of their furnaces and stoves especially adapted for the use of hotels and restaurants.

The Pease-Waldon Co., of 111 Lombard street, Winnipeg, had on view a good range of their goods, with a special display of heating furnaces. This company has just opened up in Winnipeg, and is carrying a full stock for the western trade.

The Enterprise Foundry Co., of Sackville, N.B., W. J. Copp, Son & Co., of Fort William, Ont., the James Smart Co., of Winnipeg, were also showing full lines of cooking and heating stoves.

The Amherst Foundry Co., Amherst, N.S., in addition to showing a range of furnaces adapted to all classes of buildings from the smaller house to the larger institution, had also on exhibition a fine selection of enameled ware for bath room and lavatory use, for which they have just completed a large and perfectly equipped factory.

The Canada Radiator Co., Limited, of Port Hope, Ont., showed a range of their positive circulating radiators, of which they claim they are the only makers, stating that no other maker has the positive circulation and the consequent absence of air accumulation which is the main feature in this make. It is also claimed to save at least 15 per cent. in consumption of fuel.

The Dominion Radiator Co., Limited, of Toronto, had a very fine and attractive exhibit of highly finished radiators, which drew a good deal of comment from the visitors.

An interesting exhibit was that of the Fairbanks Co., who in addition to the large display of their scales and other fittings shewed bath room and lavatory fittings.

The Siche Gas Co., who have an office at 483 Main street, had on view a range of generators in the centre of which was displayed a large generator with a capacity of some 250 lights.

NOTES.

The city of Winnipeg owns a valuable quarry of mottled limestone situated at Little Stony Mountain about five miles from the city. A deposit of clay suitable for the manufacture of fine pottery has been discovered on the Winnipeg river about 60 miles from Winnipeg. Clay suitable for the manufacture of a good quality of brick is abundant in the neighborhood of the city. Unfortunately this clay is not adapted to the manufacture of red brick.

The Board of Works of Winnipeg have recommended that the city enter into contract with an insurance company to insure its employees against accident. About $700 a year has been the average expenditure for wages to employees incapacitated through accident, and it is felt that this sum is likely to be increased by the fact that the city is constantly enlarging the scope of its operations. The cost of insurance would be about 90 cents per $100, or about $4,500 on an annual pay roll of half a million dollars. About half of this amount is proposed to be deducted from the workmen's wages.

The surtax levied by Canada on importations from Germany has cut seriously into that country's Canadian trade, but has considerably helped that of the British West Indies. For the nine months ending March 31st, 1903, Canadian importations from Germany amounted to nne hundred and fifty million pounds, while during the nine months ending March 31st, 1904, they amounted to but five hundred and thirty thousand pounds. In direct contrast to this reduction we find that the quantity of raw sugar imported from Guiana and the British West Indies increased from forty million pounds to one hundred and sixty-two million pounds in the same periods as mentioned above. A big decline has been noticeable in all other lines, the dutiable goods entering for the nine months ending March 31st, 1904, being $7,776,205, while at the termination of the similar period on March 31st, 1904, they have fallen to $5,076,383 a decrease of $2,699,822.

MONTREAL CITY AND DISTRICT SAVINGS BANK.

The building illustrated is the branch bank for which the foundations are now being excavated at the south-west corner of St. Catherine Street East and St. Timothy Street, Montreal.

The material of the facades is Deschambeau limestone upon a plinth of granite from the Stanstead Quarries. The building is fireproof the floors being of steel cased with terra cotta. The bank will occupy the ground floor and basement and will be entered by the doorway in the centre of the St. Catherine street front. The banking room occupies nearly the whole extent of the ground floor being 72 feet long and 43 feet wide. The space for public is in the middle with the counter in horseshoe form around it. A portion of the upper floors is occupied by the manager's house, the rest will be let as offices. The cost when completed will be about $70,000. The architect is Mr. A. H. Lapierre, Montreal. The builder is Mr. M. Huberdean of Montreal, the carpenter work being in the hands of Messrs. Labrecque & Mercure.

PARTICULARS OF THE SCHOLARSHIP ESTABLISHED BY THE PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The Province of Quebec Association of Architects have had under consideration for the past two years, the establishment of a scholarship in the Architectural department of McGill University. At the last annual meeting, held in Quebec, the scheme for same was submitted, and by resolution of the general meeting, was adopted. By this resolution, the Province of Quebec Association of Architects, undertakes to pay the University expenses of a student, the beneficiary being selected after a thorough course of examination. The examination or competition will take place in the rooms of the Association (5 Beaver Hall on the 14th and 15th day of September next.)

The conditions laid down by the Province of Quebec Association of Architects, are to the effect that (a) Competitors must be bona fide members in the office of an Architect, a qualified member of the Province of Quebec Association of Architects and who is also a resident in the Province of Quebec, (b) He is also required to pass the preliminary examination of the Province of Quebec Association of Architects. (c) He is also required to have passed the matriculation examination of McGill University in the Arts course.

The successful competitor shall receive tuition free of charge, in the complete course for the Bachelor of Architecture degree at McGill University, this course lasting four years.

All particulars regarding the competition can be obtained from members of the profession, the Authorities of McGill, or the Secretary of the Province of Quebec Association of Architects, R. Lacroix, No. 5 Beaver Hall Square.

A NEW METHOD OF EXCAVATING.

A Chicago contractor has hit upon a method of saving the employment of several teams of horses to haul earth out of a deep excavation. The empty wagon is driven onto a platform at the street level, the horses unhitched and the wagon lowered into the excavation by a jib crane. When loaded it is again hoisted to the platform, the horses hitched to it, and it is drawn away. The loops of the chains by which the wagon is lowered and raised are passed through the spokes and over the hubs of the wheels to prevent slipping. By this method an excavation from 15 to 23 feet deep and 110 by 200 feet in extent, was completed in sixty days.

NOTES ON THE SUPERVISION OF BUILDINGS.*

By C. F. Innocent.

In this paper I have tried to express my views as to the general conduct of a young architect on a building, embodying such information as would have been useful to me a dozen years ago.

First, let me urge upon pupils the importance of getting on to work in progress as much as possible, as this is the way to obtain a practical knowledge of construction. If your principals would allow you to visit a building from commencement to completion, say, every day or every alternate day—to act, that is, somewhat as clerk of the works—you would be greatly benefited.

The person with whom you will have most to do is the foreman, and it in well for you to remember that he is placed in his position by the builder to look after his (the builder's) interests. Much useful information can be learned in conversation with an experienced foreman, and also with the better class of workmen, such as the joiners who are "staircase hands" and the masons who set the ashlar. If you should be appointed, as I have advised, to look after work, the foreman will soon take your measure; and if he thinks you are a likely fellow for it, will try to persuade you to alter all sorts of things—of course to improve the work; such, for instance, as the benefit to be derived from the substitution of lia-lime for cement in concrete; and if you are green enough he may make such substitutions without saything to you about them. Things will go more smoothly if you always stick pleasantly and firmly to your first decision; if you know that you are right, take no notice of the builders objections that such-and-such ways are unnecessary fads and that Mr. So-and.so always has it done in some other way; you will find it best to show at the beginning that you mean to have everything done well. And whilst on the subject of foreman I would remark that some builders have an inconvenient habit of moving their foreman about from job to job; this will cause you a great deal of trouble and should be objected to.

In condemning moterials you will of course order them to be removed from the site, and if you are wise you will see them go; unless this is done it is very easy for an unheeding workman to use up the stuff—of course quite by accident. If you do not see the goods removed you should at any rate remember their appearance thoroughly, and if possible plainly mark them as disapproved.

I believe that some undesirable builders consider that disapproved material is removed if placed on another part of the site: bew are of this. Then again, when the builder assures you that the materials are the best, he may be correct in the letter but wrong in the spirit, as "best" used as a trade term does not always bear its recognized dictionary meaning. The "best" in some materials may be of quite medium quality.

In work out of town, where the builder's unable to drop into the architect's office whenever he wants to ask a question, it is almost a necessity to adopt a regular day for inspection or to inform the builder before-hand of your visit; and I believe that some architects adopt this practice with their work in town: but in such cases it is of questionable utility, as it always enables the builder to have everything on the work ready for your inspection as he wishes you to see it, and there is the disadvantage of allowing the large force of men whom he has put on the work to gladden your heart on your visit of inspection to be transferred to another job when you are safely out of the way for a few days or so. Visits at all times and any time are the best to keep everyone on the qui vive. You know that as soon as the laborer who is mixing mortar or loading up bricks in the road sees you bearing down on the job he goes inside and shouts up to the scaffold that So-and-so, whatever your name or nickname may be, is coming; then the word is passed round, and by the time you have climbed upon the scaffold the bricklayers, who have been laying the bricks nearly dry except on the face joints, are laying them as carefully as eggs, and the masons who have been packing their walls with little stones without a scrap of mortar to cover them, have flushed them all up in what seems a most satisfactory manner—until you poke into it. I suppose it is natural for everyone to go the easiest way, and you will have an early example of this when the stripped soil on the site has to be tipped; you will find most excellent reasons produced for wheeling it down hill.

When you pay a visit to a building for the purposes of supervision it is as well to go around by yourself and not be led round by a talkative foreman; in such a case I sometimes feel that work is being smothered up on another part of the building while he is engaging me in conversation; of course, it is a different matter if you go to learn what you can from him, as suggested before, and I may say here that it will be as well to ascertain from your principal what is your standing on the work. No doubt you will realize that the condemnation of work or materials by an inexperienced pupil sometimes places the architect in such a position that it is necessary to let the pupil down.

It is obviously impossible for me to describe here the numerous probable defects in the various works and materials. This has already been done in such standard works as Seddon's "Builder's Work and the Building Trades" and "Notes on Building Construction"; and various excellent articles have been published in the architectural papers. There is one point, however, which I consider does not receive adequate consideration in the text-books, that is, the correct order in which the different trades and operations follow each other. These are well known by the builder, but he does not always act up to his knowledge, considering his own convenience; sometimes, if permitted to do so, for instance, he may build the walls in one part of a building before those in another part, with unequal settlement as a possible result, or he may rush the concrete floors on while a shower of sawdust is descending from the joiners working at the roof, thus weakening the concrete; or the joiner may bridge or strut the joists as soon as they are fixed, so that the fastenings are strained with each swelling and shrinking of the timber; or a laborer with nothing to do may be set to sweep up the rubbish while the painters are varnishing, thus producing a fine frosted effect without extra charge; or various works may be delayed perhaps in the hope of slipping them all together. On contract work each tradesman usually wishes to change his men around as little as possible, to keep them at regular work, and to go straight forward and get as much work finished as is possible at one time.

I will now run through such other matters in the work requiring your attention as occur to me.

As to the commencement, some architects set out the work themselves, and others refuse to do so, but check the dimensions after the builder has set out; this is necessary because you will understand what a saving an unscrupulous builder would effect if he were to pinch 2½ in. or 2 in from each dimension of each room. The rooms should also be tested to see whether they are square. Whether the walls are at right angles may be easily tested with the measuring tape if you remember that the sides of a right-angled triangle are in the proportion of 3, 4 and 5, and their multiples of course. The heights of the rooms should also be tested.

You are not likely to be troubled much in Sheffield with bad foundations, though here and there are quicksands, in which cases the pump and concrete are a necessity. As clay is liable to swell when wet and contract when dry, with unpleasant effects to the building, you should have the footing ready before rain gets to the work. If the footings are of rubble it is necessary to see that they are well bedded on the foundations and well compacted together. Poor footings lead to subsequent cracks in the superstructure.

While speaking of the foundations I would remind you that they are occasionly omitted in places where

* Extracts from a paper read before the Sheffield Society of Architects and Surveyors.

the building inspector can be squared or where he has not yet put in an appearance.

When the drains are laid the laborers very often start to ram the filling as soon as the first portion is thrown in, with cracked pipes as a possible result; this should not be allowed. It should also be seen that pipes are clear inside especially from cement filling. In places where there is much filling, water from a hose may be used with advantage to supplement the rammer.

The mortar is a most important ingredient in a building, and as the builder naturally dislikes to waste any, the spare mortar a day or two old is very often reworked up and used in the work; as, however, its setting powers are then impaired this is not satisfactory, and you should watch and prevent it. Good mortar ought to feel greasy betweeu the fingers and dry limey on them. A builder's rough test for mortar is to take some up on a shovel and turn the shovel over; if it runs off easily he considers that it is of good quality and vice versa. In practice, poor mortar which works off stiff (by reason of the too great proportion of sand) is wetted to make it work more easily, and it is then deceptive; the waller finds mortar with poor sand (that is, lomey and clayey) most easy to work with. The lime used for mortar should be in lumps which ring when struck together. If it is sott or fallen to powder it has probably been rained upon or slaked by the moisture in the atmosphere, and should not be used for mortar.

In mixtures where lime or cement are ingredients there is a tendency, owing to the greater proportionate cost of these materials, to put in a less quantity than specified, and whether you have doubts or not it is advisable to personally watch over the mixing—especially of concrete, where the strength may be of importance; the proportion of cement may be reduced under your very eyes by the labourers putting the box for measuring the cement unto the heap of stones and sand and knocking it down, thus forcing some of the stones up into the measuring box and reducing the amount of cement. Mortar should not be allowed to set too fast (or rather too dry) and in hot weather the bricks should be well soaked in water; such wet bricks are heavier and handier to the bricklayer than dry bricks. Concrete is also not improved (but the reverse) by drying, as may take place with floors in windy weather, so that it should be kept damp until it has set. You will of course see that the bricks are properly bonded especially at angles, in reveals and jambs, and in piers. A well-bonded brick wall is much more satisfactory in appearance than one in which the joints are not perpendicular and the bricks cut about; in this respect the old eighteenth-century brickwork, where the piers and openings are all multiples of a brick, is superior to much modern work, where the piers and openings are set out on a drawing to a scale of feet and inches and the bricks have to be cut to fit.

In the walling of flues, a matter which needs careful attention is not to "throttle" them, because this is one of the most usual causes of smoky chimneys; particular attention should be paid to the flues at the bends to see that they are kept large enough; as the necessary bends themselves impede the smoke, you should see that the men in walling do not make them smaller at the angles, as they have a habit of doing.

Inferior workmen are very careless about keeping woodwork or steel joists properly away from flues and fireplaces; many fires have been caused by this, and you must carefully guard against it. There are still builders in this district who lay the joists, then build the flues around them as they come, afterwards cutting off the pieces of joists which run across the flues, leaving the ends of the joists exposed.

You will have learnt that stone should be laid in the work upon its natural bedding-plane or "quarry bed." A good way of ascertaining the bed of a stone is to douse it with water. The beds worked by the mason requires your attention to see that they are level and of full size, otherwise pieces may flush. It is rather expensive and troublesome sometimes for a builder to replace a piece of ashlar which has got chipped or otherwise damaged, and it is possible for him to patch it up very neatly and inconspicuously with cement; and I understand that very up-to-date masons stick the chip on with shellac and sand the joint, all with unfortunate results later. Keep your eyes open for this.

Some inferior builders, in order to save scaffolding on the work, only put it up on one side of the wall; this necessitates what is known as walling "overhand" and should be objected to, as it is almost impossible to plumb up the work properly; of course in some cases this one-sided walling is necessary. You should regularly plumb thewalls, as those out of plumb are unsightly and may be unsafe; besides the joiner and the plasterer cannot make a good job with them. Another point to attend to in walling is to see that the scaffolding is raised in easy stages for the wallers: some men neglect this, to the detriment of the walls. These are little ways in which the builder may effect savings that keep money in his pocket and add of course to his balance on the right side. Similar things occur in all trades—in the carpenter's, for instance, as giving all the bearing timbers an inch or so less of bearing at each end, or by making the roofs of a flatter pitch than shown on the drawings (which is easy in a hipped roof) or by setting the joists of wood or steel an inch wider apart than taken,, or by systematically omitting one joist in each room; such omissions all add up.

The ordering of extras is important, and I must warn you to be careful of what you say, as builders sometimes put their own interpretations on your innocent expressions of opinions, and when the bills comes in and your principal asks the builder who ordered such-and-such an extra, the builder, looking in his pocket-book, says, "Oh, your Mr. So-and-so ordered it on such a date"; and the results may be unpleasant for everybody. It is best for the builder ty understand that the architect alone can order extras.

I have previously pointed out the importance of seeing work carried out, and I would here emphasize the importance of getting round the builder's shops in addition to the building itself, as without a good acquaintance with workshop practice you will hardly be able to draw workable details. I have seen sections drawn for local sandstone which could only be worked in wood, or perhaps in marble, and every builder has tales of impossible details that come out of architect's offices. Not only are such visits to shops desirable for the acquisition of knowledge but they are necessary in the case of joinery, as the first coat of paint, known as the priming coat, is usually put on in the joiner's shop, and all kinds of defects may be covered up if not seen before being painted.

The principal points to notice in the joiner's work at the shop are the quality of the timber (especially as to sap and seasoning), bad joints, and the omission of labour, as in grooving and rebating, and to see that the framing is square and not winding on its faces; also, if detail drawings have been used, to see that the work as regards mouldings, framings, panels, etc., has been carried out in accordance with them. The quality of timber gets poorer as the years go by.

The places where things are most likely to be forgotten (as I will put it) are those which are dark and difficult of access, more especially the roof. I would urge you to climb up and see whether the spars and purlins and the other timbers are all properly spiked together. A client usually notices things which, though structurally unimportant, render, if not rightly built, the "very very pretty house" desired by some people unobtainable, and they should be carefully attended to—such as the quality of paint and varnish, the centering of fireplaces and windows in walls, the fitting of window sashes, and the squareness of joiner's work, irregularity in which interferes with the correct fitting of wallpaper patterns. In setting out, joiners work up to eighths of inches but consider 1/16 in. infitesimal. Bricklayers and masons do not expect to take into consideration less fractions than half inches.

The roof coverings require careful watching. Slates from the better-class quarries have not been very easy

to get lately, and unless you early bestir yourself you may be driven to accept inferior slates. Of course you will understand that with materials which have to be obtained some time before they are used in the building there is sometimes a likelihood of the builder using them for other jobs before yours is ready for them, and this may prove awkward. If the slates are to be to sample, it is as well to make sure that they are so; this, of course, applies to all other materials to sample, especially the bricks and the joiner's ironmongery.

As the slating is only a small trade I propose to consider it more completely than the others, as a type of the supervision required for all trades. The first thing to look to is the quality of the slates; they should be both hard and tough, they should have a metallic ring when struck with the knuckles, and should not fracture easily when lightly struck against wood; it water poured on the slate is soon absorbed, the slate is of course porous; slates with friable and splintered edges are generally bad; slates with green blotches in them (though the blotches do not effect the weathering qualities) are about £1 per ton cheaper than plain slates; slates get shaken on their railway journey, and if not properly packed a jolt in shunting may sometimes crack them from end to end of the truck. The slater should test every slate for soundness before holeing it, which he does by striking it on a bar in front of him or by sharply tapping it with a hammer; cracked slates, however slight the cracks are, should not be put on, as frost is sure to crack them completely. The holeing of the slates determines the lap, and this is one of those matters where a squeeze of ¼ in. will put something in the contractor's pocket. The nail-holes should not be so large that the slate will draw over the nailhead. In holeing, the slate sometimes breaks around the holes, and it not stopped the slater may turn and hole again; no slates which are broken or much chipped should be allowed. The laborer may so hole the broken slates that the broken end is hidden, when laid, by the upper slate, and there is then only one thickness of slate covering the roof at that point. The laths should be free from sap and nailed to every spar. The roofs should be lined over before lathing, and any spars which are down, or appear likely to sag, should be attended to. The slates should of course be slightly tilted towards the roof at a gable unprotected by a coping and the spars firred out before laying; the slates if in the least uneven should be sorted into thicknesses so as not to be laid at random, and any which are twisted should be rejected, as they certainly ride, although the slater sometimes says, "Oh, they'll be all right, we put the flat side downwards." Of course the heavier slates should be laid at the bottom. The double eaves-course is sometimes slipped, and if it is not the two bottom courses are sometimes nailed to a single lath. Nails, if expensive, (such as copper nails), are another matter in regard to which the slater may try to save something. Sometimes you will find nails of two weights on a job, one as specified and the other lighter. I confess that I offer no explanation of this, and fear that you will not obtain a satisfactory answer from the slaters. The nails should bulge out somewhat in the middle to get a firm hold on the lath. The joints of the slates should be virtually over each other for the sake of appearance. Occasionally there is a tendency on the part of the slater to delay the pointing of the slates until after the ceilings are plastered, on the principle I suppose that what is of sight is out of mind.

The pointing mortar should be haired or it will not stick to the underside of the laths, and some slaters do not put the the hair unless supervized; it is also a trouble to point the verges, and ordinary cement-mortar specially to point the the verges, and ordinary lime-mortai will be used if you are not careful. The ridge-niles should be set and pointed in cement-mortar, and, if flanged, the flanges should be away from the south and west in order to avoid giving a purchase to the gales from those quarters. The angle inside the ridge should be less than the rake of the roof, so as to grip it more firmly.

I have already advised you to keep your eyes on the mixing of the plaster and need not say more on the subject, except that you should satisfy yourself that the lime is well slaked. Sometimes the plasterer finds it easier to fill up a space by laths in a different direction to the rest; the plaster at such points will possibly crack, so that you should not allow him to do this. Plaster on laths should be well "keyed"; that is, squeezed between and behind the laths. I have had it explained to me by a plasterer where the key on some stoothing was absent that a key on lathed upright partitions was as unnecessary as on walls, there being no pull from the plaster, as on ceilings; but that plasterer did not make a convert, and I name the incident as an example of the numerous good reasons for doing bad work which are constantly being brought forward. It is surprising how monotonously sap and other defects in laths are declared to be "only a little stain." Of course in some cases what at first looks like sap proves to be only surface dirt.

You will find a source of considerable trouble and annoyance in the independence of some trades and the ignorance of some workmen. I refer to such matter as the cutting of bearing timbers by plumbers and gas-fitters and their kind, who, unless you warn them beforehand, will chop right through your bearing timbers without compunction if it suits them to run their pipes in such ways.

The plumber is such a monster in the popular imagination that you will be pleased to find him, on the whole, neither better nor worse than his fellow-tradesmen. However, should he be so inclined his opportunities for taking advantage of you are many, especially in the lead in gutters, flashings, ect., which should of course always be tested for size, lap weight and fall, as all of these are liable to be skimped. Also, the plumber is able when cutting the lead to give a twist with his knife which thickens the edge, so that it is better not to rely on the lead gauge but to weigh a bit of the lead and to calculate the weigh therefrom. The eaves-gutters and down-pipes should also be inspected for correct and even thickness.

The painter's trade is one of the most difficult for the architect to exercise supervision over the materials. I recommend you to make a study of these. It is well to have each coat of paint of a different shade; of course the variation need only be slight, but if you see each shade on everywhere you know that all the coats are on. This refers more especially to the constructional steel-work, where a coat is often slipped.

We have all heard of people who could not open a single window when they went into their new building and could not get the architect to attend to it for three days. Therefore, before the client occupies your building I advise you to go round and see that the sashes are not stuck with paint, that the window-fasteners work properly, that none of the keys are missing, that any damage slates are repaired, that the eaves-gutters are clear of rubbish, and (not least in importance) that the w.c. cisterns are in working order. These little things, if left imperfect, make a new building unpleasant for its occupiers and may lead to accusations of neglect on the part of the architect.

My notes must here end. But I must not conclude without saying that they do not apply to the better class of builders, with whom I hope that you will only have to deal. And as a final word of advise let me say, do not fall off the scaffold.

Colour is not merely necessary for our pleasure, but is an actual physical necessity. Absence of colour would mean the gradual deterioration of the eyes and eventual blindness.

One day the great architect Richardson was approached by a man who had only $1,500 to spend on a house. The difficulties of the problem appealed to Richardson so strongly that he took hold with zest. It put him on his mettle to produce an artistic result from purely structural conditions. But when the client announced that he could afford $3,000 he was dismissed with a wave of the hand. The great man's interest was gone.—Country Life in America.

STRENGTH OF WOODEN PILLARS.

The Building By-law for the regulation of the construction of buildings for Toronto, as prepared by the city architect, Mr. McCallum, contains a number of formulæ for the strength of pillars and beams, which we find have been worked out in tabulated form by Mr. John S. Fielding, C.E. M.E. of this city, who has been consulted by some of the leading architects in regard to this matter.

The tables cover the formulæ on pages 43, 44 and 45 of the building by-law No. 4408, as passed July 6th, 1904, and on this page we present table B which gives the breaking loads and safe loads in square wooden pillars as allowed by Kidder, Trautwine and C. Shaler Smith, for white pine, long leaf yellow pine and oak, and compares same with the safe loads allowed by the city architect in pillars of long leaf yellow pine.

Column 1 gives the size of pillar; column 2 gives length of pillar; column 3, the breaking load in tons of 2240 lbs. each, and the breaking load in pounds; column 4 gives safe load at the factor of safety of 4 recommended by Kidder for yellow pine or oak; column 5 gives safe load at factor of 6 recommended by Kidder for white pine; column 6 gives safe loads allowed by the city architect for yellow pine.

Note—Trautwine quotes C. Shaler Smith's breaking loads for moderately seasoned white and common yellow pine, with flat ends, firmly fixed, and equally loaded, as per column "3". The formula being $B = \frac{AC}{1+\frac{L^2}{3000D}}$ with C = 5000 as per Kidder also quotes from C.S.S. and gives same breaking loads, and recommends the use of a factor of safety of 4 for oak and yellow pine or C = 1250 See col. "4" and of 6 for white pine or C = 833 " " "5" Column "6 gives Mc. Callum's requirements for Long Leaf Yellow Pine Square Columns.

PREPARED BY JOHN S. FIELDING C.E. M.E. etc.

BREAKING LOADS AND SAFE LOADS ON SQ. WOODEN PILLARS
C. SHALER SMITH - TRAUTWINE - KIDDER - MCCALLUM

SHEET - B

These tables should prove very convenient for all architects and builders and should save a good deal of calculation.

The full set may be seen at this office, and Mr. Fielding is willing to supply them to any architect who may be interested.

According to the figures of the labor bureau at Washington, there have been in the last 20 years more than 22,000 strikes, involving a loss to employes and employers of over $400,000,000. The loss to the workmen themselves has been more than twice that of their employers.

—THE—

CANADIAN ARCHITECT AND BUILDER

Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:
38 ALLIANCE BUILDING, MONTREAL.
Bell Telephone 2299.
310 MCINTYRE BLOCK, WINNIPEG.
21 GREAT ST. HELENS, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements will be sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1904.

PRESIDENT	JOHN GEMMELL, Toronto
1ST VICE-PRESIDENT	J. W. SIDDALL, ,,
2ND VICE-PRESIDENT	A. R. DENISON, ,,
TREASURER	HENRY SIMPSON, ,,
REGISTRAR	W. R. GREGG, 96 King St., Toronto.

COUNCIL:

JOHN GEMMELL	Toronto
HENRY SIMPSON	,,
J. W. SIDDALL	,,
W. R. GREGG	,,
S. G. CURRY	,,
JOHN E. BELCHER	Peterborough

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1904.

PRESIDENT	J. P. OUELLET, Quebec.
1ST VICE-PRESIDENT	J. S. ARCHIBALD, Montreal.
2ND VICE-PRESIDENT	A. CHAUSSE, Montreal
SECRETARY	J. E. VANIER.
TREASURER	D. R. BROWN.

P.Q.A.A. COUNCIL.

W. E. DORAN	Montreal.
R. P. LEMAY	Montreal.
J. Z. RESTHER	Montreal.
W. J. CARMICHAEL	Montreal.
A. A. COX	Montreal.
Jos. VENNE	Montreal.

AUDITORS—L. LEMIEUX AND P. E. NOBBS.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

R. G. KIRBY, President.	JAS. CRANG.
JOHN HOLDER, 1st Vice-President.	T. CANNON, JR.
GROSGE DUTHIE, 2nd Vice-President	C. W. BATT.
DAVID WILLIAMS, Treasurer.	WM. PEARS.
W. CLARK.	A. MARSHALL.
T. W. SELF.	J. R. LYON.

WINNIPEG BUILDERS' EXCHANGE.

BOARD OF DIRECTORS

E. CASS, President. W. W. DALY, Secretary.
E. W. MURRAY, 1st Vice-President. T. D. ROBINSON, Treasurer.
G. BOURGAULT, 2nd Vice-President. ALEXANDER IRWIN, Sergeant-at-Arms.
R. S. Harrison, Angus Browne, W. A. Irish, D. Cameron, John Douglas, J. W. Morley, Thomas Cotter, J. A. Girvin, R. Watson, Victor Bouche, William Alsip, and C. H. Simpson.

MONTREAL BUILDERS' EXCHANGE.

BOARD OF DIRECTORS

N. T. GAGNON, President.	JOHN DUTHIE
EDWARD M. ROBERTS, Vice-President.	P. LAHEE
G. J. SHEPPARD, Secretary-Treasurer.	JOSEPH LAMBERT, JR.
J. H. HUTCHISON.	JAMES H. MAHER.

CHAMBRE SYNDICATE DE LA CONSTRUCTION.
(French Builders' Exchange.)
8, St. James Street, Montreal.

BOARD OF DIRECTORS.

J. B. GRATTON, President.	FELIX SAURAGEAU.
G. MENARD, 1st Vice-President	L. Z. MATHIEU.
T. CHARPENTIER, JR., 2nd Vice-President.	H. CONTANT.
ALCIDE CHAUS a. Treasurer.	E. Z. COTE
N. T. GAGNON, Secretary.	LOUIS PAYETTE.

VICTORIA BUILDERS' EXCHANGE, VICTORIA, B. C.

BOARD OF DIRECTORS:

W. D. MCKILLICAN	Chairman
E. W. WHITTINGTON	Secretary
THOS. CATTERALL	Treasurer

NOTES.

The cost of stock bricks delivered on a London site averaged about 20s. per thousand in 1776, 42s. in 1811, and at the present time may be taken at 40s. per thousand. Bricklayers' wages have gradually increased from approximately 3d. per hour in 1776 to 10½d. per hour at the present time; whilst the cost of ordinary stock brickwork in mortar has varied from £8 per rod in 1776 to £17 per rod in 1904.

Experiments were recently made in England to determine the relative strength of hand-made brick and machine-made brick, with the following results: The machine brick were dried in a drier and kiln burned, and had an ultimate strength of 197.7 tons per square foot. The hand-made brick had an ultimate strength of 125.9 tons per square foot. At those weights they were crushed. The machine-made brick showed an absorption of 7.83 per cent.

It has been calculated says a writer in The Builders' Journal, that the Colosseum at Rome accommodated 100,000 people. The height is given as from 160ft. to 180ft., but the tiers of seats inside did not rise to more than about half this height, the space above being necessary for ventilation. When such enormous crowds were packed closely together for several hours at a time on an Italian summer day, with an awning drawn over them, the atmosphere would have become pestilential if there had not been a considerable space overhead, and at least one range of open arcades for the free circulation of air.

The RICHMOHDT CONDUIT & MFG. CO., Limited
Sole Manufacturers of
Richmondt Electro-Galvanized and Navalite Conduit Tubing and Fittings
For Absolute Safety in Interior Wiring.

Rubber Matting

For corridor floors, elevators and as door mats our rubber matting holds a most unique place. It is not only serviceable every way but is extremely artistic in design.

Write us for catalogues, particulars and figures.

DUNLOP TIRE CO., LIMITED
TORONTO

BY THE WAY.

There is some talk in Toronto of appointing a supervisor of elevators. With a view to furthering the security and safety of the thousands of people who daily patronize the elevators of New York, the Superintendent of Buildings of that city is now formulating a plan for inspecting, licensing and badging elevator men. In New York there are 6,000 elevators.

× × ×

It is said that some one expressed in the presence of Cobden "the hope that some day all people might become intelligent enough to read Bacon." To this Cobden replied: "I would be happy indeed if the time ever came when all the working people could eat bacon." This was said some sixty or seventy years ago. The time has surely come when the working people not only eat bacon but also read Bacon.

× × ×

Almost every day sees evidence of some new use for concrete. So vast are the uses that it has already been put to that to-day, as stated by the Canadian Manufacturer, we are walking on it, riding on it, eating our daily bread from grain stored in concrete elevators, taking our drinking water from concrete reservoirs and cisterns, living and doing business in houses constructed of concrete, sanitating our cities with sewers of concrete, and last, but not least, enterprising undertakers are offering us the opportunity of taking our final rest in concrete burial cases, deposited in concrete tombs, surmounted by concrete monuments, sacred to our evanescent memory.

The Foundation-stone of the new Liverpool Cathedral will be laid by King Edward on July 19th.

BUILDING STRIKE IN TORONTO.

The expectation that the present building season in Toronto would be entirely immune from strikes has met with disappointment. As this number goes to press building operations in that city are almost at a standstill consequent upon a strike of the union laborers for an increase of wages from 25 to 28 cents per hour, and the decision of the bricklayers' union to support the strikers by refusing to accept material from non-union laborers. The Builders' Exchange have positively declined to grant the laborers' demand, so there exists a deadlock, which unless broken, must seriously hamper business enterprise especially in the burned district, and spoil what would otherwise have been the most active building season in the history of the city.

LEGAL.

CHRISTIE v. COOLEY.—Judgment by Justices Meredith and Teetzel in thd Divisional Court at Toronto, on appeal by defendant from judgment in County Court of Hastings in favor of plaintiff in action to recover possession of a strip of land 4 feet wide, situate in the town of Trenton, part of lot 5 on the east side of Water street. In 1883 there was erected on lot 5, which has a frontage of 66 feet on Water street, a three-storey brick building divided into three stores. The northerly part of the lot had been purchased by plaintiff from one Gordon, the remaining part being retained by Gordon, and the buildings on it, and so much of the part sold to plaintiff as was used or intended to be used as an hotel called the Hotel Aberdeen. In the conveyance from Gordon to plaintiff there was a clause by which plaintiff authorized and empowered Gordon to appropriate and use a longitudinal strip of land along the southerly side of the 25 feet conveyed of about 4 feet in width, for the purpose of erecting a suitable building, "this grant to remain in force only so long as the said building so to be erected shall remain standing on the said 4-foot strip, and no longer." The building was put up, and in 1899 was seriously damaged by fire. Held, that the building not having been entirely destroyed by fire, must be taken to have remained standing on the strip, and plaintiff was not entitled to recover.

Improvements for Toronto.

The embodiment in the report of the Toronto City Engineer, recently published, of two suggestions that have been made for the improvement of Toronto—suggestions of a couple of diagonal thoroughfares and of a lake front drive— mark that these propositions have at last reached, or are on the verge of reaching, the region of practical politics. The diagonal streets, when they are accomplished, will be one of the greatest improvements made in Toronto since it grew to be a big place on a plan that is only suitable for a small one.

There is no time like the present for a work of that kind since freedom from costly obstruction is so necessary. "At present," the City Engineer says, "there are no expensive buildings on the line of the proposed avenues." But, if the suggestion underlying this statement is that it is a necessary condition that the proposed avenues should be straight from one end to another, we could almost wish there were expensive buildings on the line; not enough to daunt the promoters, but enough to make it necessary that the avenues should have what would be a great advantage to their beauty and interest—vistas of moderate length terminating with a building, and having at that point the refreshment of a bend of some kind. College street, though of no startling beauty in its present state, offers, between Spadina avenue and the west, suggestions of how little obstruction a slight bend is in a road, and how much pleasanter it is to travel over when varied by even such slight curves as these; and, as to the question of vistas, the view from about Euclid avenue looking east to Spadina avenue, where the tower of the Broadway Tabernacle rises as a central object in the road, is far better than the interminable vistas of King or Queen streets.

We have at last discovered that constant right angles do not make perfection in laying out streets; let us go a step further and abandon the bee line too. We all want to get home as soon as possible, but there is no reason why we should not enjoy the process of getting there if we can. That a street should here and there deviate from straightness adds practically nothing to its length and takes much from the fatigue of traversing it. It is direction that is the essential consideration in a street. For this it is worth while to take pains and, if necessary, pay money; but to suffer over making a street straight, or to suffer the want of it because it cannot be made straight, is to suffer in vain, for straightness is neither necessary or desirable.

As to the lake front drive, from Queen's wharf to the Humber, it seems to be all advantage; even the making is a gain. As long as the street commissioner has innumerable cart loads of ashes and other stuff to dispose of, and no where in particular to put them, no inequality of ground is safe from his necessities; and to create a safe dumping ground for him, which will ultimately turn out a boulevard, is a happy state of affairs, equal to Sidney Smith's account of the cooking of oat meal water: "She put some dirty water in a pot and by the blessing of God it came out a pudding." And by the time this boulevard is made, perhaps the City Council will have in sight a destructor which will settle the question as it ought to be settled and has been settled elsewhere, by burning up ashes, rubbish, garbage and tin cans all together, making of them a slag harder and better than stone for making and mending the roads.

Lessons from the Toronto Fire.

The General Committee of Fire Insurance Companies have published a report which is a rather dry statement of facts conveying, however, one or two practical lessons. There is the usual complaint about the interference of overhead wires with the work of the firemen, which it is as well to keep in mind until these wires are put underground; but there are two or three practical lessons which ought to have immediate effect in influencing the manner of rebuilding the warehouses that have been destroyed. The most striking suggestion may be extracted from the account of the "Sprinklered Risks," viz: the warehouses of W. R. Brock & Co., Kilgour Bros., and the Evening Telegram. The two former were supplied with both inside and outside sprinklers, and the evidence seems to show their efficacy if the flow of water can be kept up in spite of the competition of the hydrants. There seems to be no doubt that in the case of W. R. Brock's building, if there had been fewer hose going, if the fire had been concerned only with its immediate neighbour, this warehouse, though exposed to precisely the same contact with fire as in the April fire, would have escaped burning; but in a conflagration which kept 50 streams of water running and reduced the pressure at the hydrants from 70 or 80 pounds per square inch to 37½ pounds, the water curtain from the outside sprinklers, which kept the fire off while pressure lasted, began to fail in the upper stories; "then," the report says, "it is supposed that the fire entered the risk through the upper windows at the rear." The automatic sprinklers inside kept the fire in check until the tank supply was exhausted, after which the supply to the upper floors ran dry inside as well as outside and the fire got possession of the building.

The account of the Kilgour building's apparatus is not so clear. It had the advantage of a larger tank supply for the inside automatic heads, and the outside heads are said to have had a steamer connection auxiliary to the supply from city pressure; but it is not said whether the steamer connection was made use of, or whether the safety of the building, and the credit which is due to it of having stopped the fire at that point is due to its superior apparatus or to the good fortune of having had as its exposing neigbour on its uninjured side, a lower building than the Brock warehouse had. One point is clear, that, where the building did take fire, its advance within was held in check by "good division walls;" but that is a precaution well known, however little used. The immediate example furnished by these buildings is the efficacy of sprinklers if their efficacy is secured, and the simplest way to secure it would be to supply these, as well as hose pipes, with water from the fire engines. It would require a point of application at a comfortable distance from the fire; not up a lane but on the street; and on the edge of the sidewalk rather than against the building.

The Telegram building, though sprinklered, did not get to the point of opening the heads. The fire was successfully fought with inside hand hose, and special mention is given to good work done with a length of hand hose attached to a roof hydrant. This sounds like a good thing to have but not to rely upon. It is good to stop small beginnings, but the flame that reaches across a street would make short work not only of a hand hose but of those who operate it.

A second lesson is that a longitudinal fire wall hinders only a transverse fire; and a transverse approach is no longer the only thing to be expected from fire. Buildings are now so much higher than formerly, in relation to the width of the road, that it is only a question of the direction of the wind whether the flame from a burning warehouse will attack its adjacent neighbour or its neighbour across the street. Fire walls should run all round a building and the roof drain to the middle.

The great lesson of the fire, however, is one that was taught before, when the McKinnon warehouse took fire through its windows from the Globe office across the way. A building is not fire-resisting unless its windows are protected. With protected windows any brick building with fire walls and a reasonable roof would be hard for the fire to get at; without them a building may be as fireproof as a stove and burn as well. It is the stock that burns. Most stock burns well and much of it is very inflammable. There is nothing to prevent fire running through a fire proof building from front to rear, if there is nothing but glass between its stock and a fire across the road.

There is one other question of some interest:—How far is a portable fireproof safe a certainty in case of fire? There are rumours of safes being burst open by their fall from an upper floor. Whether this is founded upon evidence or conjecture there is certainly, in one statement of the Insurance Companies' Report, some food for conjecture as to the fate of safes which fall to the cellar. The report says:— "The hardware stocks were in very bad shape; hardened steel tools, gun and rifle barrels and heavy shelf hardware being found in masses, sometimes of several tons weight." How is a safe likely to fare that falls into the sort of fire that could make one mass of steel implements such as are described above! There should certainly be some hold in the wall for portable safes, to keep them out of the cellar. What answered once will not necessarily answer now; for with bigger buildings we have bigger fires.

THE ARCHITECTURAL ASSOCIATION AND ITS WORK.

SECOND ARTICLE.

In a previous article some account was given of the habitation of the Architectural Association and its Day School, which takes care of preparatory and junior work. This work is carried on further by an Evening School, necessarily held at that time because it is for working students.

The Evening School, like the Day School, is a serious affair with a comprehensive curriculum and paid lecturers of experience; and the hours of attendance for students, 6.30 to 9.30, for four nights a week, means serious application on their parts.

"The complete curriculum" (to quote the Association Brown Book) "is arranged in two divisions with some extra subjects and extends over four years. There are in each division two parallel but distinct courses, viz.: a course of Lectures and Classes, and a course in the Studio." This means that the theory of Design, Construction and Sanitation so far as it can be taught by word of mouth is thus taught in the course of Lectures and Classes, and the instruction so given is worked out on the drawing board by practical exercises in the Studio. These parallel "Courses" of Lectures and Studio work are again sub-divided into "Divisions," not for the further classification of subject but simply that the whole subject matter may be cut into four convenient lengths to occupy the evenings of four winters. There are thus two divisions of lectures and two divisions of Studio work, and they are usually taken alternately, so that Division I. of the Lectures is followed by Division I. of the Studio, which runs parallel with it; and Division II. of the Lectures by Division II. of the Studio.

What is accomplished is laid down in the curriculum as follows:—

Division I. Lectures and Classes. 1. Greek and Roman Architecture and Classic Ornament. 2. Elementary Principles of Building Construction. 3. English Architecture to A.D. 1500. 5. Outlines of Mediæval and Renaissance Architecture in Europe. 6. Elementary Physics as applicable to Building, Formulæ and Calculations, Stresses and Strains. 7. Plane and Solid Geometry.

Division I. Studio. 1. Freehand Drawing. 2. Descriptive Geometry. 3. Perspective. 4. Ornament: Drawing from the Cast. 5. Greek and Roman Architecture: The Orders, their optical corrections, characteristic forms, mouldings and ornament. 6. Mediæval Buildings and their Accessories. 7. Building Construction. 8. Elementary Architectural and Decorative Design.

Division II. Lectures and Classes. 1. Materials, their Nature and Application. 2. Construction. 3. Hygiene (Drainage and Water Supply). 4. Hygiene (Materials and Construction, Ventilation, Lighting, and Heating.) 5. Professional Practice, including the London Building Act, Valuations, Dilapidations, Light and Air, Specifications, Approximate Estimation of Cost, Contracts and Agreements. 6. Lectures and Field Demonstrations on Land Surveying and Levelling.

Division II. Studio. 1. Stereography and Sciagraphy. 2. Architectural Perspective. 3. Ornament and Shaded Drawing from the Cast. 4. Studies in Ancient, Mediæval and Renaissance Architecture and Design, founded upon examples in these styles. 5. Designs and Working Drawings of Modern Buildings. 6. Internal Decorative Work. 7. Time Sketches.

The Extra Subjects are:—1. Lectures and Classes on the Elements of Quantity Surveying, including the Preparations of Estimates. 2. Instruction in Modelling. 3. Elementary and 4 Advanced Water Colour class. 5. Ornament and Colour Decoration. 6. Class for Sketching and Measuring. 7. Lectures and Demonstrations on Perspective. 8. Discussion Section.

The latter comes under the head of extra subjects chiefly in virtue of its special fee of half a crown. It is simply a paper reading meeting, held on the fifth night of the week, but it is made safely instructive by securing the presence of a person of special experience in each subject under discussion, to sum up the debate.

This it is not too much to ask a busy man to do occasionally, but with the exception of this, which strikes few places far between, there is no volunteer work connected with the evening school. There is also a School of Design and Handicraft which resembles what in America is usually called a Sketch Club, except that to the School of Design and Handicraft it is intended to add a course of workshop demonstration. This school has, for each of its two divisions, a monthly meeting presided over by an architect drawn from a large Committee of Visitors. This also is volunteer work; but with the exception of this and the chairmanship of the Discussion Section there is no volunteer work asked for in the teaching work of the Association. In fact one might almost say there is no volunteer work asked for at all, for, though the president and other honorary officers must no doubt give their minds to the affairs of the Association during their term of office, they are not called upon to do any clerical work. For this there are salaried officers.

This is the central fact to be extracted from an inspection of the doings of the Association; nothing is expected for nothing and nothing is given for nothing. It is recognized that no one can afford to give time and labor such as is required for real teaching, unless he can get or help to get his living thereby. This is the fundamental basis of the schools; they offer something worth having. The right to ask for the fees which carry the work along and the readiness to give them are consequences. It should, however, be noted that the kind of immediate inducement, which young people and even their parents require to seduce them to a proper valuation of the necessity of high training, is present in the examinations of the R.I.B.A The letters signifying associateship and fellowship of the Institute are becoming more important to architects than ever, as the demands made upon the architect's capabilities become more complex, which is only to say that it is the need of education that is recognized by young architects rather than the necessity of letters. The Institute's examinations have come to take exactly the place they ought to take—a place which our examinations ought to take—a convenient standard for testing efficiency; a definite landmark to aim at in an outlook which extends to such hazy distances that it is satisfactory to have something obtainable in view, which, when reached, is a guarantee that one is in the right way and is getting on fast enough. This is the advantage that the Institute is to the Association. The Association, however, does not live by reason of this,

but because its work is good; and it is good because it is paid for. The condition precedent to paying teachers must be receiving fees, but more certain than this is it that the condition precedent to receiving fees for teaching is offering the sort of teacher that can only be got by payment. There are virtuous circles as well as vicious circles, and this is one. However, the Association circle was started in its round, it is working all right now; in both the day school and the evening school the fees received from students more than pay the salaries of the instructors—in the day school by nearly as much again.

The same quid pro quo principle holds in other doings of the Association. They publish a Sketch Book which has grown to be a valuable production—one that our architectural associations would do well to subscribe for. The first thing that occurs to one who knows the difficulty of keeping up anything that depends upon voluntary work is "how is the supply of 72 plates a year kept up?" The answer is simple—they are paid for. The subscription for the sketch book is a guinea a year, but four drawings, i.e., one for each quarterly part, entitles the contributor to receive the Sketch Book for a year and ten extra copies of each of his drawings. This is a good bargain for all concerned. Every advanced student or young architect makes some measured drawings during the year, either in his own country, which is full of invitation, or in the little holiday on the continent which is now so common. The obvious thing to do is to make the drawings 17¼ x 13½ inches to suit the Sketch Book and take some pains about them that they may be accepted. It means a guinea in pocket for doing what one was going to do anyway, and ten copies of one's work instead of one. To the Sketch Book it means a competition of drawings, instead of labour to get them; to the subscribers generally, the same competition must give better and better drawings every year; and the virtuous circle is completed by the impulse given to holiday studying by this reward for its immediate results.

One might go further in investigating the proceedings of the Association and still find this method of reciprocal benefit: the travelling student, for example, is anything but free in using his scholarship. He must submit his route for approval; he must send back a journal; he must give up his drawings for exhibition, and the Association have the choice of one to keep. The Association thus get something out of their gift, but the benefit is still the greater to the student who makes better use of his scholarship under these conditions than he otherwise would.

It is evident that the first consideration in providing for the instruction of students is to provide a good thing; it is only thus it will obtain support. It may be necessary to begin with money in starting the circle, as the good thing must be presented to students in order to get support, and the cost of presentation is the first step in establishing the circle of advantage. But for this, if for anything, it is fair to ask for aid from the public or the rich. Indeed, a loan might be all that is necessary, for, if similar methods bring similar results, the financial statement of the Architecturnl Association shows a profit on teaching that would make it easy to pay back soon a sufficient initiative loan.

It may be the better for definiteness to have the Association figures before our eyes; without supposing that either fees or salaries must necessarily be the same over here. The fees for the four regular divisions of classes and studio come to about $26.63 a year, and the Sketch Club 65 cents a year additional. The extra subjects spread over the four years come to about $6.42 a year. That is to say the cost to the student, who takes every opportunity offered, averages $33.70 a year and amounts to $134.80 for the four years. The cost to the Association in 1903-4 was $2,401.42, in lecturers' fees for the evening school and the students' fees received exceeded this amount by $590.

W. A. Langton.

THE TORONTO BUILDING STRIKE.

After more than a month of idleness the striking builders' laborers in Toronto have gone back to work at the same rate of wages as they were receiving prior to the strike. The bricklayers who supported the strikers have also resumed work. The net result to the strikers is the loss of thousands of dollars in wages which might profitably have been spent in providing fuel and other necessary supplies for the approaching winter. Owners of new buildings under construction have been put to great inconvenience, and the general trade of the city injured.

The strike was entirely unwarranted, in fact was nothing short of a "hold up," and was generally so regarded. Public sympathy was unmistakably against the strikers, and some of the daily papers found courage enough to denounce in plain language the action of the unions. The absurdity of the demand made by the laborers' union for a wage of 28 cents an hour is shown by the fact that the rate paid in Winnipeg, where labor is scarce and cost of living nearly double what it is in Toronto, is only 22½ cents. Furthermore, it would manifestly be unjust to pay such a wage to unskilled labor while paying only 30 cents an hour to skilled carpenters who, in addition to the years spent in acquiring the technique of their trade, must lay out a considerable sum in the purchase ofexpensive tools.

The bricklayers were under no obligation to stand by the striking laborers and thereby violate their agreement with the Builders' Exchange. On the contrary, they should have shown their disapproval of what they knew to be an unjust demand. Had they done so, the strike would have collapsed at a much earlier date and they would have been money in pocket. To show how little their support was appreciated it need only be stated that while they were walking the streets many of the striking laborers were working at 20 cents per per hour as helpers to concrete and other contractors.

As a means of avoiding these untimely interruptions to trade the Builders' Exchange should insist that in future agreements to govern wages must date from the first of January.

H. C. Standage writes to the Decorators' and Painters' Magazine that one of the easiest methods of cleaning a sponge that has become fouled by wiping the surface of paint or varnish, is to dissolve 1 oz. of permanganate of potash in 5 parts of water, and steeping the sponge in the fluid for fifteen minutes. Then squeeze out the fluid and allow to dry. When dry, put the sponge into a solution prepared by dissolving ½ lb. of hyposulphite of soda and 1 oz. of oxalic acid in 1 gallon of water. Allow the sponge to soak in this bleaching fluid for 15 to 20 minutes; then take out and rinse well in cold water, and hang up on a line until dry.

NORTHWEST NOTES

Branch Office of The Canadian Architect and Builder,
310 McIntyre Block, Winnipeg, September 12, 1904.

WINNIPEG BUILDERS' EXCHANGE.

The Exchange held its fifth monthly meeting on the evening of the 6th inst. and had a record turnout. The meeting proved a very interesting one and considerable business was transacted.

New members continue to be brought in, nine names being added to the list at this meeting.

A number of enquiries were received from outside points regarding business here. One from Toronto touching on the question of laborers' wages was discussed.

One important motion passed was to the effect that no member of the Exchange should sign any form of contract other than that approved by the Exchange—"The Uniform Contract." Any member violating this resolution will be subject to the penalty imposed in the by-laws, providing among other things for expulsion from membership.

Another motion passed was to the effect that no member of the Exchange should figure on any contract where another member had work in the same line unfinished without the consent of the first contractor.

An interesting paper was read on "Sentiment in Building" by Mr. E. S. Estlin.

Altogether the meeting was very satisfactory and showed that the Exchange is rapidly getting into shape and doing good work.

BUILDING OPERATIONS.

That the building trade is still very brisk is evident by the large number of buildings permits issued during August, viz., 181. There are still a large number of houses to be built before the season closes. The total amount of building so far this year has reached about 7½ million dollars; being by far the heaviest season Winnipeg ever had.

Yet with all the increase there has been in houses there seems to be as great a scarcity as ever of houses for rent, and rents remain much higher than they were last year. This speaks well for the increase in the population of the city. One needs to take a drive over the city to realize the vast amount of building that has been done this year. In all parts—north, south, east and west—houses have gone up and new streets have been opened. In Fort Rouge, the favorite residential part of the city, this improvement is especially noticeable.

Numerous wholesale merchants who have been increasing their accommodation are getting their buildings near completion, although no doubt it will be the end of the year before the finishing work is all done. There is hardly a wholesale building in the city that has not had two or three stories added to it—a proof that the original builders anticipated a great growth in the wholesale trade of Winnipeg and prepared the foundations in the first place so that additions could safely be added to their buildings.

A very interesting and busy scene is the work on the new subway on Main street at the C.P.R. station. Work here is progressing very rapidly. The cement and concrete walls and piers are almost finished, and a large number of supports for the concrete arches have been placed. The excavating of the roadway is finished and the electric street railway tracks have been run as far down as possible so that the through car service with the north end of the city may be quickly established. The C.P.R. track has to be raised yet as it is not at its full height, but that will be done quickly when the time comes.

The contractors found that the excavating took more time than such work usually takes as the steam shovels usually used for this class of work could not be employed in the tough clay here which had therefore to be dug out by hand which makes it a much slower and more expensive process.

Eastern contractors putting in tenders for work in the west would do well to bear in mind the great difference there is in the soil in the west, the tough clay taking much more time to excavate. Other peculiar differences exist which add to the expense of working.

A RECORD FLAG POLE.

A flag pole designed to be placed on the top of the new Union Bank building is the longest ever brought into Winnipeg. It was imported from Washington Territory by the Sprague Lumber Company. It is 86 feet 11 inches long, and tapers from 12 × 12 inches at the butt to 7 × 7 inches at the point.

PERSONAL.

Mr. Herbert H. New is the latest addition to the list of architects in Winnipeg, where he has established an office in Molsons Bank building. Mr. New has recently arrived from Boston where he was engaged with the well known firm of C. & H. Blackall. He is much impressed with the prospects of Winnipeg.

Mr. H. B. Rugb, who had just taken an office at 367 Main street, Winnipeg, as our last last issue went to press, is now settled and has already submitted some attractive drawings, and is on the eve of starting his first commission.

BRICK MAKING AT BRANDON.

The Brandon Brick and Lumber Company, Ltd., which was incorporated several months ago with a capital of $100,000, is on the eve of completing the installmeot of their plant, and expect to be in full operation very shortly. This company have purchased the right of the "Huennekes System" for Western Canada. The product will be a dry pressed brick of sand and lime, baked in a chemical steam cylinder, the special advantage claimed being the production of a brick of a stone like character at a moderate cost.

The sand is first passed through a drying machine, the heat for which is supplied by the exhaust steam from the boiler. It is then carried by a band conveyor into a tubular grinder at the entrance of which is a unique apparatus which acts as a measuring or weighing machine and at this point the correct quantity of lime is admitted, to mix with the sand passing into the grinder. From this machine the two materials are conveyed into a mixing machine where a sufficient quantity of water is added to slack the lime. From thence the material is elevated to a storage receptacle immediately over the brick press of sufficient capacity to hold one day's working, the mixing of one day being held over until the following.

The "Press" has 3 moulds and has a working capacity of 15,000 bricks in a day of 10 hours.

After passing through the "Press" the dry brick is wheeled on trucks into the immense cylinder, which measures 62 feet in length by 6 feet diameter, provided with a steaming apparatus, with small perforations the whole length of the cylinder; into this cylinder the bricks are placed and the steam is applied at a pressure of 100 to 125 lbs.; thus, steam bakes the brick; there is a small "reservoir" at a certain point in the steam fittings, into which is placed a chemical mixture which has the effect of adding to the steam as it passes through the properties which give to the brick its special hardness. The company is expecting to do a very large business, as they have a large supply of sand available in the district, at a minimum cost of production.

The directors of the company are:—Dr. McDiarmed, Mr. H. Sampson, Mr. J. Clark, Mr. H. A. Rose, Mr. A. R. McDiarned.

MANITOBA'S STONE SUPPLY.

The present season will probably close as the "record" season in Winnipeg's building, but as pointed out in previous issues, many more buildings would have been completed, had there been available a more plentiful supply of material.

Undoubtedly one of the main causes of this lack lies in the fact that supplies have to be drawn from outside, and in many cases from far distant points. It was therefore welcome news that there was evidence of an unusual quantity of good material in the shape of lime stone within easy reach of the city. It was to demonstrate this that the Garson Quarry Company, Limited, chartered a special train on Saturday, August 27th, and sent out invitations to all interested in the building trades, to visit their Tyndall quarries, an invitation which resulted in a goodly array of prominent Winnipeg building men sallying forth prospecting.

The quarries were reached after a smart run about three in the afternoon.

There are three separate quarries at work, one in operation by the Garson Quarry Co., and two by the Gunn Quarry Co. The first to be examined was that of the Garson Company. Excavations have been made to a depth of 55 feet and reveals me very useful stone for all ordinary purposes. It is interesting to note that the contractors for the C.P.R. Hotel at Winnipeg have made arrangements to draw the whole of their supply from this quarry. The quarry works cover a space of some 2½ acres. The company have rights extending over 200 acres and tests thus far made are said to have proved 70 acres to be good building stone.

Great interest was evinced in the various details of working, the steam drill coming in for no small amount of attention, work-

ing as it did with the greatest ease, making a 2" hole 8 ft. deep in the solid rock; dump drills, hand drills, and all the methods were here seen in operation. On one side of the quarry was fitted up a complete manufacturing plant, a machine for cutting, a turning machine, and a large staff of stone cutters were at work preparing stone for buildings now in progress. There was also a row of some 8 lime kilns, with a total capacity of 2,000 bushels per day.

Turning to the adjoining quarries, about ½ mile distant, conclusive evidence appeared of the general "stone" character of the district. Although in these, development had not progressed so rapidly, still the stone brought to light was equal in every respect to that previously considered. The method of chiseling here was somewhat different to that in the other quarries, a large steam chisel being in operation, working at a pressure of 80 lbs. and capable of chiseling 100 ft. per day of 10 hours.

After a very pleasant and instructive afternoon, the company were entertained at an excellently spread table, provided by the

"Garson Quarry Co." Conversation naturally turned upon subjects of interest to building men, ending with a few informal speeches and votes of thanks.

There is little doubt but that the result of the afternoon's trip will be an increased interest in the use of local stone for Winnipeg's future buildings, and should the transportation question prove as satisfactory as the supply is adequate, a large and profitable business is in sight.

The present quarries have only been in operation 5 years and at the present rate of development they are expected to last well into the century.

PLASTIC DECORATION.*

By John D. Crace, Hon. Associate R.I.B.A.

The lecture was very fully illustrated by plaster models and casts lent by Messrs. George Jackson & Sons and by the South Kensington Museum authorities, by a series of large mounted photographs lent by Mr. B. T. Batsford, and by numerous lantern slides, of which five and twenty had been placed at the lecturer's disposal by the A. A., Camera Club. Having alluded to the prehistoric use of cement and plaster as a uniting substance and a protective surface material, the author gave reasons for his inference that stucco was used decoratively in an early period of Greek history. Among the many wonderful revelations of Mr. Arthur Evens's explorations in Crete are the stucco decorations in relief of the walls of the Palace of Knossos which was destroyed before 1500 B.C. Beautiful specimens of decorative stucco-work have been unearthed in excavating the ancient sites of Rome and the surrounding country. The author referred to those at the baths of Titus discovered in the sixteenth century, to those at Herculaneum and Pompeii, and to the decoration of two sepulchral chambers discovered on the Via Latina, dating about A.D. 160. In the Farnesina grounds remains of buildings have been unearthed with stucco reliefs unsurpassable for elegance and refinement of execution. One great value of these works is the lesson they teach us in the adjustment of the actual treatment in execution to the nature of the material. The whole surface speaks aloud of the ready and dexterous use of fingers and tools on a light plastic material. One almost imagines the stucco yet moist, still impressible to the touch. It is as if some fairy goddess had found it soft and lightly fingered it. There is a sense of evanescence about it, whilst the charm of perfect attainment remains.

The author then turned to a beautiful but very different growth of plaster decoration developed under the Mohammedan conquerors, describing the decorations of the great ninth century Mosque of Ibu Tooloon at Cairo. In the Arabic art of Egypt plaster continued to be used as an important factor in decoration during the next five centuries. The ornamentation of the domes and the use of a fine stucco in low-relief ornament, as a preparation for gilding and colour on the wooden beams of its flat roofs, are especially noteworthy. The palace of the Alhambra is the very apotheosis of plaster—of plaster casting carried perhaps to excess of richness and elaboration, but never losing its true quality of ornament designed purposely for casting. The beautiful effects of a mere repeat casting, the author thought, were attained because (1) the designers thoroughly understood grace of line and how to fill their spaces; (2) they never lost sight of the fact that the work was to be cast; (3) most important of all all, the repetition did not include the representation of natural objects, for it is where representations of nature are concerned that repetition is offensive.

In European art during Mediæval times we get little glimpse of the decorative use of stucco until the 15th century. An original and striking example is to be seen in the drum of the dome of San Eustorgio at Milan, the work of Michelozzo Michelozzi, of Florence, said to have been executed in 1462. In the second half of the 15th century Bernardino Pinturicchio was making considerable use of the low-relief enrichments,

*Abstracted from a recent lecture before the Royal Institute of British Architects.

not only for the mouldings with which he divided the surfaces he had to decorate, but as ornamental features within the paintings themselves. A few years after Bramante was at work on St. Peter's. His investigations, says Vasari, resulted in the discovery of the method of preparing stucco employed by the ancients, the secret of which had been lost in their ruin, and remained concealed ever since. Vasari relates how Raffaelle and Giovanni da Udine went together to see some subterranean chambers then just discovered in excavating the Baths of Titus. Giovanni was so much impressed by the stucco decorations with which they were covered that he devoted himself to their study, and reproduced them with so much grace and facility that there was only now wanting to him the knowledge how to compound the stucco. At length, by compounding finely-powdered white marble with the lime from white travertine, he succeeded in producing the stucco of the ancients. Raffaelle at once caused Giovanni to decorate all the vaultings of the Papal Loggie in stucco. Pierino del Vaga, another of that wonderful band of young artists in the Vatican, stands pre-eminent as an ornamentist and as a decorative colourist; his stucco-work has a quality of fine decorative appropriateness, both in design and scale, that has been surpassed by none. Of his bolder conceptions the great ceiling of the Sala Regia is a fine example. Alessandro Vittoria was one of the best-known stucco-workers in the latter half of the sixteenth century. His work under Sansovino at Venice, in the Libreria, and in the Scala d'Oro of the Ducal Palace are characteristic examples of his style.

Francis I. attracted to France some of the most capable of the Italian artists skilled in stucco. Primaticcio and Il Rosso came about 1530, and their wonderful stucco decorations at Fontainebleau long influenced French design and French sculpture. Niccolo dell' Abbate followed twenty years later, and then his three sons, the youngest becoming after a time the director or manager of these decorative works. Their work is a fine field for the study of what may be done in stucco, and it was the parent of the rich decorations of Louis XIV.'s reign, which, in their turn, became the model for civilised Europe.

Henry VIII, was also very successful in securing the services of able artists in England, many of them pupils or relations of those who were at work on the masterpieces of the Vatican. Pietro Torrigiano, who was among the earliest, completed the bronze monument of Henry VII, in 1519. It was to the Palace of Nonsuch that the new stream of talent was directed; although not a vestige of it now remains, the names of some of the men who adorned it are a guarantee that the work was neither coarse nor commonplace. As to the question lately raised about the external panels of Nonsuch being in stucco, the author said there was not the smallest doubt on the subject. There were plenty of examples done more roughly within the next seventy or eight years which remain to this day, in spite of exposure and neglect.

External decorative work in plaster continued to be a feature of many English houses down to the end of the 17th century. But the interior was the more important field, and from the time of Nonsuch for a century no house of any pretence was without its elaborate plaster ceiling and frieze. Admirable in many ways as these old English ceilings are, few of the men who did them had either the art or the skill of the Italians, who made ornamental plaster work popular. The latter endeavoured to make their work perfect in modelling and finish. Each figure was a work of art. In the English plasterwork, however, scarcely a figure can be found that is not more or less barbaric in execution, and the minor work, effective as it is, is often greatly wanting in grace of line and in intelligent modelling.

The next step in English plaster-work leads straight to the Classic work of Jones and Wren. The gap caused by the Civil War made the change more complete. Building operations after the Great Fire opened the way to new men and methods. French and Italian plaster-workers were again invited to England in Charles II's reign. Besides the work in St. Paul's, St. Stephen's, Walbrook, and other city churches, the chapel of Trinity College, Oxford, may be cited as a good typical specimen of plaster ornamentation. A feature of some of the plaster decoration of the end of the seventeenth century is the elaborate modelling of fruit, flowers, and foliage in full relief, often in parts quite detached from the grounds and either supported by wires imbedded in the plaster or by small sticks of tough wood. This work, full as it is of artistitic ingenuity and clever modelling, was by that very ingenuity departing from any true principles of stucco-work, and therefore hastening the decay of the art: A notable example is the ceiling of the chapel of the Royal Hospital, Kilmainham. The next modification of style was largely due to Kent. In his designs the plaster ornamentation is mainly used as architectural enrichment, bold in treatment—sometimes too bold for the space, but effective in its way. Following closely on Kent's work came a flood of plaster ornament derived from the French work of the time of Louis XV. This was sometimes very good—often straggling and purposeless, yet not without a certain elegance. The best of it was at least partly modelled, but the greater part was cast and fixed. With this style stucco modelling practically came to an end. All that followed was cast and fixed. The change of style brought about by the brothers Adam was due to the same influence which has produced the detail of the Vatican Loggie and the Villa Madama—namely, that of the antique stucchi in the excavated ruins in Rome. The difference in the result may be thus accounted for. Giovanni da Udine studied them, as an artist by endeavouring to produce similar work with his own hands. Robert Adam, as a draughtsman, copied them on paper, as did probably the Frenchmen through whom France adopted the style. It was undoubtedly elegant, and the effect refined; and, since the method of reproduction was mechanical, it lent itself to extensive use.

Much good plaster work has been done in the last half of the 19th century—always in the form of attempts, sometimes very successful, to reproduce a past style, and by casting. "Fibrous plaster," introduced since 1861, is a valuable innovation, and presents immense advantages. It does away with the danger of enormous overhead weight, and requires so much the less timber structure to carry it; it can be executed quickly, and it dries quickly. The facility of plaster work is at once its recommendation and its danger.

It is, perhaps, well to be sometimes reminded that the simplest materials have not been scorned by the greatest men, and that the finished result of any art pleases not only by the talent bestowed on it, but by the fitness of the limitations which the artist has imposed on himself.

Mr. R. Phene Spiers, F.S.A., proposed a vote of thanks to Mr. Crace, and expressed his concurrence in the lecturer's condemnation of the imitation in modern plaster work of the wavy surfaces and crooked lines found in old examples, and due in them to indifferent technical skill. He held that all plaster decoration should be executed on curved surfaces, as not only was a perfectly flat surface less pleasing to the eye, but it gave the appearance of sagging.

Mr. G. H. Fellowes Prynne, in seconding the motion, remarked that stucco was not satisfactory or permanent as external work in this damp and variable climate. Plaster decoration should only be employed under cover, and then in low reliefs on plane surfaces. For such mural decoration in low relief there was now a very large opening.

Mr. W. Aumonier observed that the harmonious effect of 16th-century plaster was due to the fact that both the moulding and the modelling were entirely handwork, whereas in most of the present day decoration all the mouldings and outlines were rigidly and mechanically produced, and even much of the modelling was executed in facsimile.

In replying to the vote of thanks, which was carried bo acclamation, Mr. Crace said he agreed with Mr. Spiers that very low relief decoration appeared to greatest effect on a curved suface; but for all that the artistic merit of a subject did not depend upon the angle at which it was seen.

DESIGN.

A conference dealing with arts and crafts was held in connection with the Bradford Exhibition a few weeks ago, when Mr. Walter Crane, the well-know artist-craftsman, gave a lecture on "Design."

Mr. Crane first showed the linear resources in abstract which were at the command of the designer, and went on to demonstrate some of the rules which were observed in different classes of designing. Coming to speak of the importance attached to beautiful things, he observed that, as a domestic nation, fond of their homes, and exercising constant and often highly-cultured taste in respect of their decoration, considering carefully the colours which they cared to live with, the patterns with which they would have to put up day in, day out, the form of the furniture, and all these things, Englishmen had been forced to consider whether they should not make the things of their homes beautiful as well as reasonably useful. A sort of national shyness, or shirking from display had laid a rather wholesome check on exuberance in ornament.

Turning to speak of the style which is known as the "New Art," Mr. Crane observed that that style had had a very sudden rise, but its origin was quite traceable. If there was a public analyst for art, he would rather like to catch some of the most extravagant specimens of the "New Art," and send them to the analyst in a bottle for examination. The sources of the details could quickly be determined. The whole style might be described as a species of rhetoric in design—a rhetoric which was rather meaningless, and which was much repeated, sometimes in skilful hands but very often in unskilled. It had had, however, great influence over the decorative art of our time, both at home and on the Continent. It could not be denied that it had about it certain dramatic power. But one could not live too far from Nature for long without suffering in health, and the forms reminded him of plants which, under artificial stimulus, had been drawn up into very long stalks, with flowers only on the extreme end. Although it was "New Art," it seemed to him already in decline. It had exhausted its own stock of expressions.

Mr. Crane urged students to study Nature, observing that they need not be inappropriately naturalistic but the more they studied natural forms the more varied and interesting would be their design. A new fashion had now come in, a kind of secondhand Louis XVI., with early Victorian mixed. This pretended to go to Nature, but a real rose would blush to find itself by one of the rose garlands of the newest art. Mr. Crane proceeded to speak of the modern movement toward beauty in craftsmanship, and pointed out that a necessary constituent in the beauty of an object was that in its design there should be full recognition of the characteristics and limitations of the material which was used in its production.

There was, he observed, in all manufactures a tendency to imitate, and to exert skill in trying to step beyond the nature of the material, which found acceptance at the hands of those who, if they could not have costly things, would rather have a cheap imitation than nothing, or than something which was simple. Under the industrial organisation of the last century the ideal had been mechanical precision—quantity rather than quality. A different idea was asserting itself more and more.

Where England was behind was not in the capacity for producing beautiful and individual objects, but in the realisation of the national importance of art—art as the expression of the life of the community. England did not give sufficient opportunities to her sculptors to do great things. Instead of perpetuating the form of an eminent citizen in senatorial garb—frock coat and so on—his portrait might, he ventured to suggest, be confined to a bust or to a medallion, and the artist might be called upon to exert his skill in a heroic group or composition typifying the life's work of the citizen who was honoured. England had a great deal to learn in that respect from her neighbours of France and Germany.

In conclusion, Mr. Crane commended the drawing which he had that day seen at one of the Bradford schools, and emphasised the importance of the teaching of drawing well. Education, he pointed out, did not consist in learning various facts, and he feared that in schools not enough play was left to the imagination. English people were over-industrious, and were afraid of the pleasures of the imagination.

A SUBSCRIBER writes: "I have to fix a brass curb on a marble curb around a dining-room grate. The brass has already been fixed once or twice in cement, but this has been broken and the curb has come out of its place. Which would be the best way to fix it?" The best plan would be to rivet iron bars on to the standards, pass them through the marble curb and bolt to the underside of the hearth.—Builders' Journal.

THE McCLARY MANUFACTURING COMPANY'S NEW WORKS AT LONDON, ONT.

These new works, situated on the north bank of the Thames river, at the corner of Adelaide and Trafalgar streets, and devoted exclusively to the manufacture of stoves and furnaces, contain many features in the way of special arrangement and equipment, a description of which it was thought would prove interesting and instructive to architects and engineers. The buildings consist of a moulding shop, a stove mounting shop, a storage warehouse and an independent power house.

The new works have been laid out with the object of simplifying and expediting as much as possible the sequence of processes of the manufacture of stoves and furnaces, and the equipment has been arranged in such a way that the material in process of manufacture is received at one end and shipped from the other end of the works, thus avoiding the necessity of any piece in process of manufacture being carried back to any point it has once passed.

One of the most important elements of the thoroughness and efficiency of the plant is contributed by the electrical equipment, the various machines in the works being arranged in groups, similar machines being in one group driven by a single line shaft driven by an individual motor attached to the ceiling or placed in such position above the floor as to be entirely out of the way. The result of this distribution of power is that the line shafts have been placed in the most advantageous positions to give ample room, light, and convenience. The difficulty so frequently met with in industrial establishments, namely, the laying out of the line shafting and the counter shafting in such a way that all will form a unit driven by one or two engines, has been entirely dispensed with, with the result that the company have one of the cleanest, best lighted, best ventilated and most efficient industrial plants to be found anywhere.

FIG. 1.—VIEW OF POWER HOUSE, SHOWING RAILWAY SIDING FOR COAL DELIVERY.

The buildings were designed by and erected under the supervision of Messrs. Moore & Henry, architects, London, Ont., and the power plant and electrical distribution system and equipment were designed by and installed under the supervision of Mr. Roderick J. Parke, consulting electrical engineer, of Toronto.

The moulding shop or foundry, in which the first process of stove construction takes place, is situated at the north-west corner of the property, and is 200 feet wide by 220 feet long, one storey high, built of white brick with concrete foundations and having a roof of the saw-tooth variety, as shown in Fig. 2, the glass sides of the roof being exposed to the north, giving all the light desired without exposing the workmen to the direct rays of the sun. The moulding shop has a concrete floor; across the south end and divided from the moulding room is the milling room containing the tumblers and core ovens. A Colliau cupola having a melting capacity of 10 to 12 tons of iron per hour is located in the centre of the moulding shop, as shown in Fig. 4. The charging platform is constructed of steel and concrete to support a track from the cupola to the north wall of the building at which the pig iron and coke are received from the railroad cars which are taken in on a siding especially constructed for the purpose, the moulding shop being located in such position as to take advantage of a hill at the north side, thus enabling the railway cars to be shunted up to the level of the charging platform. The progress of the material and product through the moulding shop is direct and continuous, toward the mounting shop.

The mounting shop, located about 200 feet east of the foundry, is 307 feet long by 32 feet wide, two storeys in height; the walls are built of solid concrete, and the floors of steel and concrete, being of absolutely fire-proof construction. Between the foundry and the stove mounting shop is the pattern storage warehouse, 130 feet long by 40 feet wide, one storey high.

All of the motors in the mounting shop are supported on or near to the ceiling so as to occupy as little useful room as possible. Each motor is controlled by a Cutler-Hammer motor starter with automatic no-voltage release. Push buttons are installed at various points so that a motor can be instantly stopped in the event of an accident occurring or a quick shut-down becoming necessary.

Direct current is distributed throughout the buildings to the various motors and lamps, at 230 volts. The works are illuminated by means of Adams-Bagnall 3.5 ampere 230 volt arc lamps, and 230 volt incandescent lamps. Separate circuits are provided between the power house and the shops so that separ-

ate control is had at the switchboard for the lamps and motors in the moulding shop and the mounting shop. Sub-distribution panels are located in the shops for the separate local control of incandescent and arc lamp circuits and certain of the motor circuits, thus

FIG. 2.—EXTERIOR VIEW OF FOUNDRY, SHOWING "SAW-TOOTH" ROOF CONSTRUCTION.

affording a very flexible system with a minimum amount of wiring and maximum simplicity.

The power house is located on the north bank of the River Thames 300 feet south of the mounting shop. It is built of white brick one storey high with concrete foundations and concrete floors, and is 104 feet long by 35 feet wide, with a wing 56 feet long by 44 feet wide for the storage of coal, this wing being in such position as to take advantage of the natural gradient, permitting the railroad cars to be shunted to the north end of the coal house so that the coal can be dumped directly from the cars into the coal bunkers.

The boiler equipment consists of three 100 h. p. standard internal fired Scotch boilers, manufactured by Messrs. E. Leonard & Sons, London, Ont., and constructed for 160 lbs. working steam pressure. They are 15 feet 9 inches in length over all, exclusive of the smoke box. The shell of each boiler is 84 inches in-

FIG. 3.—INTERIOR VIEW OF FOUNDRY, SHOWING CUPOLA AND CHARGING PLATFORM.

side diameter, made of 19/32 inch steel plate. There are 56 tubes 3½ inches outside diameter and 12 feet 6 inches long. Each boiler is equipped with a Morrison suspension type corrugated steel furnace, 40 inches inside diameter by 12 feet 2¾ inches long and 7/16 inches thick, and a Jones underfeed mechanical automatically operated stoker, which with the induced draft equipment affords an available capacity of 150 h.p. from each boiler when required. When the fourth boiler, for which space is provided, is installed, the total plant capacity will be 600 h.p.

A Green fuel economizer has been installed to operate as a part of the steam plant. This economizer contains 1920 square feet of heating surface and is divided into 40 sections, each section containing four tubes 4 9/16 inches external diameter and 9 feet long. The economizer is provided with a safety valve 2¼ inches diameter and a blow-off valve 3 inches in diameter, and the front or face of the machine consists of 10 sectional removable covers 2 feet 5 inches wide with 2 inches of asbestos lining. Each section of the economizer was subjected to a hydrostatic test of 350 lbs. to the square inch before erection, and after the economizer was erected it was subjected to a hydrostatic test of 200 lbs. per square inch.

The advantage of the economizer is apparent, in view of the fact that when the plant is operating at full load the temperature of the feed water is raised from 112 degrees Fah., at which temperature it is received from the exhaust heaters, to 260 degrees Fah., at which temperature it is delivered to the boilers.

FIG. 4.—EXTERIOR VIEW OF STOVE MOUNTING SHOP, SHOWING CONCRETE CONSTRUCTION.

The reader will notice on looking at the illustration the absence of a tall stack or chimney. Draught for the boiler furnaces is obtained by means of forced and induced draught combined, the forced draught being supplied from a 30 inch three-quarter housing bottom horizontal discharge Buffalo Forge Company steel plate fan delivering air at 2 ounces pressure into an underground pipe leading to the underfeed stokers. This fan is driven by a 6 in. x 6 in. horizontal high speed engine supplied by the Robb Engineering Company, Amherst, N.S.

The induced draft is created by a duplicate fan apparatus furnished by the Buffalo Forge Company; the equipment consists of two 8 foot full housing-up blast steel plate steam exhausters, each being driven by a direct connected 4½ inch by 5 inch single vertical double acting engine having the cylinders below the shafts. The equipment is provided with water-cooled bearings, a sheet steel smoke chamber and a Y smoke outlet connection upon which the stack rests, the stack being 47 inches in diameter and 15 feet high, the top of the stack being about 40 feet above ground.

The smoke breeching connecting the boilers, fuel economizer, and induced draft apparatus, is provided

with by-passes and dampers arranged so that the economizer can be cut out of the smoke circuit at any time and the smoke turned directly from the boilers and through the induced draught fans to the stack. The induced draught fan engines and the stoker engine are controlled separately by two Foster automatic steam pressure regulating valves, so that when the steam

FIG. 5.—INTERIOR VIEW OF MOUNTING SHOP, SHOWING ERECTING DEPARTMENT AND "HOT BLAST" HEATING CONDUIT.

pressure falls below a given point more steam is admitted to the engines, and their speed is increased with a corresponding increase in the draught, with a reversal of this operation when the steam pressure goes above the pre-determined point for which the valves have been set.

The water used for condensing is drawn directly from the Thames River and is allowed to run to waste, as in view of the adoption of other methods of utilizing the waste heat the advantages of having a hot well are so small that its use is not warranted. Owing to the poor quality of the Thames River water for boiler feeding, the feed water supply is obtained from a creek across the river, this creek furnishing practically pure water. A special conduit was the city water mains to provide a reserve for use in the event of repairs being required for the regular feed-water supply system. The feed water is forced by the pumps, through the heaters, thence directly to the Green fuel economizer, thence into the boilers. By-passes are provided in the feed water line so that any heater and the economizer can be cut out of service when required. A feed water thermometer is provided at the outlet of each heater, also at the outlet of the economizer and on the main feed water line between the heaters and the economizer, thus enabling the attendant to determine instantly and accurately the value of the work each individual heater is doing, as well as the net results of the combined operation of the feed water heating system.

The engine exhaust is arranged as follows: The 75 h. p. engine and 50 k. w. dynamo unit is used only when a melting-heat is in progress and when required for lighting the works. The exhaust from this engine is connected directly to its condenser, but a branch and valves are provided so that the condenser can be cut out of service and the exhaust turned directly into the works heating system. An automatic relief valve to the atmosphere is provided between the engine and the condenser, this valve being adjustable to give any desired back-pressure within ample limits when the steam is being supplied to the factory heating system. The exhaust from the 185 h. p. tandem compound engine can be turned directly into its condenser, or directly into the factory heating system, or to the atmosphere, as may be required. A branch is provided to the 200 h. p. feed water heater, which latter can be run under a vacuum or at atmospheric pressure or cut in or out of service, as may be required.

The exhaust steam for the induced draught fan engine, the mechanical stoker engine, the condensers, and the boiler feed pumps, is run into a common exhaust pipe leading into the 80 h. p. heater, on the outlet of which is placed a vent pipe to the atmosphere, with an adjustable back-pressure valve on it. The exhaust steam from the auxiliaries is not condensed since it is utilized to better advantage in heating the feed water passing through the 80 h. p. heater. The temperature of the feed water from the small heater with the plant running under normal conditions averages 210 deg. Fah., and the temperature of the feed water passing through the 200 h. p. heater while the large engine is running condensing averages 110 deg. Fah. When the large engine is running non-condensing the temperature of the feed water averages 210 deg. Fah. It will be apparent from the above description that the auxiliary plant as designed affords full facilities for operating the power plant under the most economical conditions during the winter and summer season, in

FIG. 6.—VIEW OF PORTION OF BOILER ROOM, SHOWING 100 H.P. INTERNAL FURNACE BOILERS WITH UNDERFEED STOKERS AND PORTION OF STEAM PIPING.

addition to permitting advantage to be taken of the exhaust steam for heating the shops in winter, and of condensing in summer.

The switchboard equipment consists of two generator panels and a feeder panel, of blue Vermont marble, 65"x24"x2", with sub-panels 25½"x24"x2", each generator panel being equipped with an I-T-E "Dublarm" automatic double-pole 250-volt circuit breaker, con-

nected so that it is impossible to accidentally short-circuit either generator, the function of the circuit breakers being that the single poles of each breaker open and close independently of each other, so that in the event of a short circuit or overload remaining on the generator circuit after the breaker has been thrown open, the closing of the second pole will immediately open the other. These circuit breakers were made by the Cutter Electric Company, Philadelphia, and are adjustable for a capacity of 50 per cent. above and below the rated capacity of the respective generators which they are intended to protect. A double set of busbars with double throw switches has also been provided on the switchboard and the connections arranged so that the generators can be operated independently or in parallel. This provision has been made with the object of providing an independent control for lamps and for the 50 h.p. cupola blower motor in the foundry, as it is necessary to vary the speed of this motor at times, the variation of speed being secured by manipulation of the generator rheostat on the switchboard. When the cupola is in operation, the 50 k.w. unit and the 50 h.p. motor operate as an independent combination, a special pair of mains being run from the switchboard to the cupola for this purpose.

The circuits between the dynamos and the switchboard are run in trenches built into the floor, these trenches being covered with cast-iron checkered plates. The conductors are rubber-covered and are supported

FIG. 7.—INDUCED DRAFT FANS, SHOWING STOKER ENGINE BELOW PLATFORM, AND PORTION OF GREEN FUEL ECONOMIZER AT LEFT HAND.

upon split porcelain insulators held in position by iron clamps fastened by screws to 3″ × 3″ vertical wood strips set into the concrete flush with the walls of the trenches. The outgoing circuits from the power house are run underground through a brick tunnel. Forming a part of the switchboard is a gauge panel upon which are mounted a 10″ engine room clock, an 8″ boiler pressure steam gauge, an 8″ steam gauge connected to the receiver between the high and low pressure cylinders of the compound engine, and two 8″ compound vacuum and back pressure gauges, one connected to the exhaust pipe from each engine.

For furnishing compressed air for operating the pneumatic hoists and other pneumatic machinery used in the works, a class D-2 10″ × 16″ × 12″ Canadian Rand

FIG. 8.—AIR COMPRESSOR AND MOTOR.

Drill Company air compressor has been installed. This compressor is driven by belt from a 40 h.p. Westinghouse direct current motor. This compressor is designed as a compound machine, the high-pressure or 10″ × 12″ halt being installed at present, the foundations being so arranged that the low pressure or 16″ × 12″ half can be installed when required. The capacity of this compressor is 446 cubic feet of free air per minute at a speed of 120 revolutions per minute.

A RHAPSODY OF THE NEW ART.

O catfish maid with the taffy arms—
A loop and a curve and a daub of greeo—
Flaunting the flow of thy molten charms
On the side of a soup tureen.

Art thou a girl or a goop or a fish,
Or merely a tinted thought,
Like a chocolate caramel stuck to the dish
And into thy semblance wrought?

O, limpid lips' insipid peace—
A loop and a curve and a daub of green—
O, rapture covered with verdigris
And Art that is sight unseen!

A lily grows on a silver stem
That twists as a bedspring might,
In the ruby shade of a Turkish hem
It holds an electric light.

O, lines of beauty, O, lines of care!
O, art of the new, new fad!
Loop, loop the goop of the limbs and hair.
Till the drinkers of fudge go mad!

—Wallace Irwin in N. Y. Globe.

Cement production in the United States in 1903 amounted to 28,454,140 barrels, according to the U. S. Geological Survey. Of this amount 20,897,973 barrels were Portland cement, 7,030,271 barrels were natural cement and 525,896 barrels were slag cement. The amount made in 1903 was about 2,700,000 barrels more than the output in the preceding year.

The effect of maintaining a higher standard of purity of the air breathed could not better be illustrated than by the following statement of facts: By improved ventilation the death rate has been reduced in children's hospitals from 50 to 5 per cent., and in army hospitals from 23 to 6 per cent., while prison records show, in one case, a reduction from the yearly average of 80 to 8. In the army stables of the German Government better ventilation has reduced the death rate among the horses from 19 to 1.05. Such facts speak for themselves.

AN EXTRAORDINARY FEAT IN HOUSE MOVING.

The Engineering Record describes how the John Eichleay, Jr., Company, of Pittsburg, Pa., transplanted a brick residence to a new site 160 feet above the one on which it originally stood at the foot of a cliff, without in any way injuring the building. The face of the cliff behind the house was terraced by excavating in it six cuts making an equal number of horizontal platforms about 90 feet long and from 10 to 20 feet wide, affording level seats for the successive tiers of cribbing. The excavation was nearly all in solid rock, which was drilled and blasted with light charges of dynamite, thirty men being busy on it during the entire progress of the work.

Holes were cut through the end foundation walls and 12 x 12 inch longitudinal needle-beams about four feet apart were inserted in the usual manner. They were parallel to the face of the cliff and reached through from wall to wall of the main part and the wing. Main 12 x 16-inch sills were placed under them and carried, on each side of the front and rear walls, 12 x 12-inch longitudinal sills which supported the latter with pairs of short transverse 10-inch I-beam needles. The main sills were jacked up to lift the building clear of the foundations, which were then removed and the ground was leveled to receive lines of cribbing under each of the main sills. Each line of cribbing was located on the center of the sill and consisted of a continuous row of cribs made of 6 x 8-inch timbers about 3½ feet long. The bases of the separate groups were made horizontal, but at irregular heights, offset to correspond with the surface of the ground, and were leveled up so that the upper courses were in exactly the sale planes. There were in all eight lines of cribbing perpendicular to the face of the cliff, one under each main sill. Two lines of cribs supported each end wall of the main part of the house. Two more lines were spaced at equal distances between them and two carried the end and centre of the wing. About three hundred 5-ton jacks were set under the sills bearing on the second course from the top of the cribbing. These were divided into thirty groups of from eight to twelve each, from three to five groups being located under each sill. At a signal given by blowing a whistle, one man started at the end of each group and gave each jack in succession one-half turn. After all the groups had been turned, another signal was given and the men returned to the starting points, screwing each jack another half turn and so on back and forth, simultaneously screwing the jacks so as to raise the building uniformly about one-half inch at each round trip.

The building was thus raised about 14 inches in less than two hours. A new course of cribbing timber was then laid in the space between the last course and the sills, and the jacks were simultaneously slacked off sufficiently to lower the sills to bearing on it. The jacks were then screwed down, set one course higher, the building raised another fourteen inches and so on. As the building was raised the lines of cribbing were extended so as always to reach beyond it to the gradually receding face of the cliff where new cribs were started on successive footings leveled to receive them. In every eighth or tenth course longitudinal timbers 20 or 30 feet long were used to bind the cribs of each line together, and the next course above them usually contained several long transverse timbers reaching through, and built into, the next line of cribs to bind the two together and insure their lateral stability. The cribs were also braced by inclined shores and were X-braced by wire ropes reaching from the top to the bottom of each panel under the main part of the house. In each panel between cribs vertical planks were spiked to the longitudinal sills, and horizontal longitudinal beams were bolted to their lower ends to carry the suspended working platform of loose transverse planks. These were arranged at the proper height to be convenient for the workmen to build the cribbing and operate the jacks and rollers. They were always maintained in the same relative position as the building was raised, and when the floor planks approached the cross timbers, the latter were picked up and placed on top of them so that when the scaffold was raised a little higher, it engaged them and lifted them off. The main sills supported a stiff-leg derrick with a boom commanding the full length of the building and operated by a hoisting engine at the bottom of the cliff. This derrick delivered the crib timbers to the men who were always busy on the suspended platforms.

After the building had been raised to a height of about 60 feet a pair of long track timbers were laid on top of each line of cribbing, and wooden rollers 8 inches in diameter and 4 feet long were inserted about 12 inches apart on centres between them and the sills, and the building was moved back on them about 40 feet to the face of the cliff. This was accomplished by two nine-part tackles with 2-inch rope and fall lines about 1,200 feet long. In the front of the building the tackles were attached to vertical oak timbers bearing at the upper end on the saddle pieces over the needle-beams, and at the lower end on the main roller timbers. The tackles passed under the house and were anchored at the face of the cliff to horizontal longitudinal timbers bearing across the runway timbers under the rollers. The lead lines were carried through snatch blocks to two 2-horse-power windlasses on top of the cliff.

After the house was moved, the crib-work which had been released was taken down and used in building up the second section of cribbing from the roller level to the top of the cliff as the building was continuously raised the remaining 60 feet to the top of the cliff. It was then rolled over beyond the face of the cliff and moved in the usual manner on inclined runways to the new location. The total weight handled was about 1,200 tons and no mishaps occurred during the progress of the work. All the plant and materials used were regular stock from the contractor's yards.

WALLPAPER AND HANGINGS.

Apart from considerations of the design and the appearance of a wallpaper under certain conditions, the architect should also consider the means of its manufacture and the materials of its composition, says a writer in the Architectural Record. Wallpapers and hangings may be divided into two main classes: (1) the printed papers, and (2) the flock and relief. With regard to the first, the printing is done either by hand or machine. In the hand printing the colors of the different blocks are not applied until after the color is dry, while in those printed by machine the various colors follow on wet, the whole design being printed as the roll of paper passes through the machine. It will, of course, be easily understood from these conditions of manufacture that hand-printed papers have greater sharpness and accuracy, each color being distinct and separate, while in the machine work they frequently run together more or less. The hand-block printer also has the advantage of being able to print two or three pieces at very little extra expense, whereas with machine-made papers the cost of "setting" a machine is so considerable that it does not pay unless a large quantity of paper is printed, the consequence being that after a year or two it becomes impossible to repair a room with machine-printed paper or to repeat the same design if desired. The flock papers are made by printing on the paper with a cementitious material and then scattering finely chopped wood fibre evenly over it. As each different color requires to be worked separately and strewed with wood fibre, the process is, of course, very expensive. The coverings in relief are prepared by a variety of special processes which are to be referred to the general principles of embossing by the application of pressure or moulding when in a plastic or flexible condition, either separate or combined. With regard to the materials of which wallpapers and hangings are composed, the colors are either distemper or oil. The distemper colors have a tendency to fade in sunlight, though much depends upon the colors chosen and the composition. Papers printed in oil colors always darken and yellow—i.e., the ground does—giving a dingy and shabby appearance unless the designer has made allowance for it. When new, they are often good in effect, though, I think, they never equal distemper papers. They have one advantage over distemper in allowing a tint to be gradated by the mezzo-tint process. Papers printed in oil colors may be twice sized and then varnished so as to allow washing, but a varnished paper is always unpleasant. Papers sold as varnished ready for hanging should be avoided, for they are varnished with a quick-drying, hard, white spirit varnish, and have very little durability. If a varnished paper is desired it is best to varnish it after hanging. One little point worth noting in connection with varnished papers is—that allowance should be made in the paint of the room for the yellowing of the varnish.

In wallpapers from reputable manufacturers there is no danger to be apprehended from poisons in the colouring matters, but from the smaller manufacturers a warranty should be obtained that the green papers are free from arsenic (even then it is best to test them oneself) and that papers of other colours are free from copper or mercury. "Pulp" papers have the back of the paper the same colour as the ground of the front. Papers in which the ground or pattern, or both, have a sheen as of satin are known as "satin" papers, and are made by mixing Spanish white with the colouring matter and polishing it with a burnisher; such papers are very susceptible to damp, and should be protected by a lining-paper. The materials of which the coverings in relief are composed are mainly paper, wood, fibre and cloth. One well-known hanging which claims to be the only material solid both in colour and relief is composed of oxidized linseed oil and wood flour mixed with colours and a few minor ingredients. Another is made by placing wood pulp in moulds to a considerable thickness; others are composed of asbestos, canvas or silk refuse.

The American Window Glass Company controls an invention for the manufacture of that article for which they are said to have refused ten million dollars. It is designed to reduce the cost of production by dispensing with blowers, gatherers and snappers, all of whom are high-priced men. For a year past, three of the machines have been secretly operated, all imperfections and drawbacks eliminated and overcome and the company has installed 12 of them in the old De Pauw plant at Alexandria, Ind., this plant being newly equipped throughout for the making of glass.

Dr. William Collinridge, medical officer of health to the Corporation of London, has issued a report in which he suggests that all owners of kitchens and above-ground bakehouses be informed that a standard of requirements has been drawn up by the Corporation and that upon complying with this a certificate will be granted. The proposed standard requirements are set out at the end of the report. They stipulate smooth impervious floors, walls and ceilings, double covers to inspection chambers, minimum height of rooms 8ft., minimum cubic capacity 1,500ft. and not less than 400 cub. ft. per employee, temperature not to exceed 80 degs. Fahr., each bake-house oven furnace to have a flue for carrying off sulphurous fumes and an outlet for heat and steam immediately above the oven door; underground kitchens to have inlets for ventilation at least 12in. above the footway or ground level, proper lavatory and w.c. accommodation, storage water cisterns with dust-tight fixed covers, shelves to be 2in. from the walls and hose to be provided for washing the room efficiently.

AN ENTIRELY CONCRETE BUILDING IN HALIFAX.

On the illustration sheets of this number is a building owned by A. M. Bell & Co. in Halifax, N.S., in which the walls and piers are entirely of concrete and steel bars. This forms quite a precedent in Canada, as in the majority of cases of buildings of concrete construction we usually find the facings of brick, stone or marble, but in this building all the face work and even the mouldings are of concrete.

The walls were constructed in the usual way by building up wooden sheeting on each side and filling in the concrete. They are twenty inches thick to the top of the first floor, sixteen inches to the top of the second and twelve inches in thickness for the remaining three upper stories, the building being five stories high. The piers on the two frontages are four feet wide and two feet thick.

The mouldings which stand out strongly in the illustrations were formed by building up the reverse mouldings in wood, thus forming the concrete mouldings in one piece with the walls.

Cracks, due to the expansion and contraction of the concrete, were prevented by building up the main piers in both frontages separately with boxes built in recesses to receive the ends of the lintels which were built in later, thus forming joints where the movement due to expansion and contraction could be taken up. These lintels, as also all the piers and walls, were reinforced by iron beams and twisted steel rods, while iron rods were laid horizontally in the walls every four feet of the height, and twisted iron rods were run vertically the full length of the piers.

The concrete used in the construction was of various grades and qualities, that used for the walls being composed in the proportion of seven parts of sand and gravel to one of cement; that in the piers of five parts of sand and gravel to one of cement, while the mouldings were constructed of cement composed of equal parts of sand and cement.

Within the interior of the building is a large two-storey vault with double 8-inch cinder concrete walls.

The building was designed by R. A. Johnson, architect, successor to Hopson Bros. of Halifax, N.S., and constructed by Geo. B. Low, contractor, of Halifax.

PUBLICATIONS.

A fourteenth edition, revised and rewritten, of the Architects' and Builders' Pocket Book, by Frank E. Kidder, C.E., Ph. D., has been published by John Wiley & Sons, New York. It contains 1650 pages, size 6½x3⅞, with 1000 illustrations. Price, in morocco binding, $5.00.

The McGraw Publishing Company, 114 Liberty Street, New York, have recently issued an instructive work by Frank W. Skinner entitled "Types and Details of Bridge Construction." The book comprises 294 pages and is liberally illustrated. It is printed on heavy paper and substantially bound in cloth. The price is $3.00.

When melting size for distemper keep it well stirred, and it should not be allowed to get beyond a lukewarm state. If very hot when mixed with the whiting the distemper will be "runny" when cold instead of a jellified mass.

NOTES.

Mr. Peter Brass, one of the oldest and most highly respected architects of Hamilton, Ont., died a few days ago following an operation in the general hospital of that city.

Two strikers were picketing the entrance of an alley during the strike at the factory of the Kellogg Switchboard & Supply Company in Chicago. A non-union man came out of the factory and started across the street. One of the strikers picked up a brick. As he looked at it an expression of disgust came over his face and he threw it down.

"Why didn't you throw it at the scab?" asked the other striker.

"Because it's a non-union brick."—The World's Work.

The New Century Refrigerator & Manufacturing Company, Limited, of Dundas, Ont., have their large new factory completed and in full operation. It is splendidly equipped with the best and most modern machinery and systematized so as to reduce the amount of labor to the minimum, and is one of the most complete wood-working factories in Canada. There are large and extensive dry kilns by means of which all lumber will be thoroughly seasoned before being manufactured. The company will make a specialty of hardwood veneer doors with built-up bodies, which they claim are unshrinkable and are guaranteed not to warp or twist. They are made in modern designs, artistic in appearance and equal in construction and finish to any door on the market. They will also give close attention to architects' special designs of doors and trims. Agents will immediately be appointed in the different districts, and they will doubtless find their products a profitable line of goods to handle.

FIRE-PROOF GLASS WINDOWS

THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

The Engineering News has found eighty-two gas plants supplying heat to customers through a distributing system. Fourteen of them have central heating systems. The Progressive Age says in regard to this list, that "Although there is a great deal of head-shaking going on over gas companies entering other lines of business, yet the fact remains that if a product can be sold it should not be thrown away. This holds good not only for residuals, but for waste heat and steam, and coke breeze as well. Through the flues and up the chimneys of gas-works go many millions of heat units which might be sold at a profit if a way were found to put them into marketable form. We pay money for heat units, and when we waste heat units we waste money. Whether we are compelled to spend as much as we will save depends upon the method, but the success or otherwise of these central heating plants will solve a very important problem in public supplies and private economies.

REMOVAL NOTICE.

On the first of November, 1904, the Winnipeg office of this Journal will be removed to Rooms 720 and 721 of the new Union Bank Building. This building, which is just nearing completion, is thoroughly fireproof and in construction and equipment is the equal of any on the continent.

A standing invitation is given readers and friends of the Journal to call when in Winnipeg. Any possible information or assistance will be gladly furnished them.

Belgian vs. British Structural Steel.

The large trade which a few years ago was being done in Great Britain by Belgian and German manufacturers of steel joists and girders, is reported to have been killed as the result of tests and inspection to which the material was subjected by users in Great Britain. The trade is now in the hands of British firms whose product is not so cheap, but is uniform and reliable in quality.

Safety of Elevators

The Coroners' Jury appointed to enquire into the circumstances attending the death of Dr. McPhee, of Ottawa, who was recently crushed in an elevator, returned with their verdict of accidental death the following recommendation :—"We would recommend that the city by-law governing elevator operators be changed, so that no operator be less than eighteen years of age, and no operator be engaged without first having a certificate as to competency from the building inspector."

Building in the West

Several Toronto contractors are finding a profitable field of operations in Winnipeg, where building is more active than in any other city on the continent. The value of building permits issued for the nine months ending September 30th, was in round figures $8,000,000, a sum in excess of the expenditure for this purpose in any other city in the United States or Canada, not excepting New York. In spite of this large expenditure, it has not been possible to meet the demand for houses. During the past summer a considerable number of families lived in tents. Some of these have been unable to secure other accommodation, and are at a loss to know where to find shelter during the coming winter.

"Fire-Proofed" Wood.

The Mayor of New York as the result of strong pressure has withheld ratification of the ordinance recently approved by the Board of Aldermen of that city compelling the use of fire-proof trim in the erection of new buildings above 75 feet in height. Builders asserted that the ordinance would be valueless except to the

manufacturers of so-called "fire-proof" wood. The term "fire-proof" they claim to be a misnomer as applied to wood. Experience is said to have demonstrated that its fire-proof qualities are dead within three years at the longest. We have seen samples of wood impregnated with chemicals, which could not be burned, but cannot say anything regarding the durability of the process. If not durable, the use of such material, involving as it does considerable extra cost, would be of little value, and must prove a hindrance to building and an added burden in the form of higher rentals to the public. On the other hand the great losses caused by fire renders necessary building laws that will insure as far as practicable the use of non-inflammable materials.

Building Regulations.

A clause of the new building by-law of Toronto provides that walls of new buildings exceeding 35 feet in height shall be built in cement mortar. In the case of the first church building to be erected since this by-law came into operation, the walls are 28 feet in height, but the gables exceed 35 feet in height. The city architect has ruled that the entire walls must be laid in cement mortar. This will entail an extra expenditure of $500 in the construction of the building. The architect offered to increase the width of the foundation walls by 4 inches above the thickness required by the by-law for ordinary lime mortar construction, but the city architect insisted that cement mortar must be used throughout the entire construction. This would seem to be a doubtful interpretation of the provision of the by-law and one that does not appear to agree with common sense. The gables of the building in question do not support any weight and constitute but a very small percentage of the total wall area. This case emphasizes the fact that not only must building by-laws be very carefully framed in order that they may be equitable, but also that they should be interpreted in the light of common sense if hardship and injustice is not to result from their operation.

Patents on Skyscrapers.

Mr. Leroy S. Buffington, an architect of Minneapolis, has brought suit in the United States Circuit Court of Appeals at Chicago against the National Safe Deposit Co., owners of the first National Bank building now under construction in that city to recover damages for alleged infringement of a patent granted to him covering a method of employing a steel skeleton in building construction. Mr. Buffington's attorneys claim that his patent, which was granted on May 22nd, 1888, is a valid one, and broad enough in its claims to cover all the buildings of the steel skeleton type erected throughout the United States in recent years. The claim for infringement is specially based upon the use of essential features of the patent, viz., a shelf or projection on each story to carry the outer walls for the succeeding story, whereby expansion and contraction due to changes of temperature cannot endanger or seriously affect the structure, and a continuous post consisting of a plurality of plates, placed side by side and diminishing in number towards the top; another feature is the employment of non-conducting packing between the veneer and the steel skeleton. Mr. Buffington proposes to institute other suits for a similar purpose. The outcome will be watched with much interest by building owners, architects, contractors and all others in any way identified with the erection of buildings.

Sand Bricks.

At several points in Canada experiments are being made with the manufacture of sand bricks. What advantages are claimed for these bricks above those manufactured by the ordinary method has not been learned. A recent test in Europe of ordinary lime-sand bricks of good quality and clay made bricks of similar quality demonstrated that the latter were less absorbent. The present would appear to be an opportune time to make known the advantages of sand bricks and to place them on the market, in view of the exceeding scarcity and high price of ordinary bricks. In Toronto at the present time best quality common bricks are reported to be selling as high as $14 per thousand. This fact is causing owners of property and especially speculative builders to hesitate about starting the erection of new buildings this autumn. It is estimated that by reason of the enhanced prices for materials and labor, the cost of building this year has exceeded that of 1903 by 10 to 20 per cent.

The Winnipeg Exhibition.

Financially the Dominion Exhibition held recently in Winnipeg must be counted a success, the management having in hand a cash surplus of $6,482. The attendance was also measurably satisfactory, totalling 200,000 persons. Viewed from the exhibitors' standpoint, and as the precursor of successful Exhibitions in the future, our information is that it left much to be desired. The arrangement by which the exhibits were placed in the rear and the side shows in front, worked out badly for the exhibitors. We have been told that a large percentage of visitors never got beyond the side shows and left the grounds without seeing the exhibits at all. Consequently the thousands of dollars expended by eastern manufacturing firms desirous of bringing their products prominently before the notice of the people of the west, were to a large extent wasted. The exorbitant charges for accommodation demanded by hotels and boarding houses militated against the success of the enterprise and is calculated to have an even more serious result in deterring persons who did attend from visiting future Exhibitions in the same city. The lack of interest shown in the exhibits, combined with the excessive charges for accommodation decided a number of the eastern exhibitors to quit the Exhibition before the closing day, while visitors living within reasonable distance of Winnipeg made a point of spending only a part of one day in the city, and of returning home in the evening. Before the people of Winnipeg can hope to induce either residents of the west or outsiders to attend in large numbers any future enterprise of this character they must give assurance that care will be taken to remove the causes that that have occasioned dissatisfaction this year.

The Lac du Bonnet Mining and Brick Company, of Lac du Bonnet, Man., reports an increasing demand for bricks. Their output this year has been over five million and a million of these have been fine pressed brick for face and finishing purposes. They are now engaged on an order for 1,000,000 brick for the new power house of the Winnipeg General Power Company, and another order for 100,000 for the new immigration sheds at Winnipeg.

OPENING LECTURE OF THE DEPARTMENT OF ARCHITECTURE, McGILL UNIVERSITY.

By Prof. Percy E. Nobbs.

Strictly speaking, this lecture belongs to the third year of the course for the new degree of Bachelor of Architecture and as its theme is one of very general application and paramount importance to designers, I have ventured to invite the presence of others besides my third year students.

In naming the course The Building Trades the intention has been to avoid the use of the word Crafts, which is perhaps more applicable to the subject matter about to be covered, because that word has during the last twenty years come to be associated with a certain amateurishness in the field of art which the ancient craftsmen would have been the last to approve. Also, because during the last decade the "Arts and Crafts Movement" as it has been called, has tended more and more to countenance certain eccentricities in design which its loudest and most strident supporters have dubbed "originality". Having set up a brazen calf in the wilderness so to speak, the cult of the new art (or L'Art Nouveau) has resulted, and the word "craft" is never out of the mouth of those who follow that way.

I do not propose at the present juncture to set forth my views on the training of designers further than to name to you the mental elements which I think are combined to form the mental image of an unmade and rightly designed possible object. This high function of conceiving an unmade thing is the nearest to actual creation that man can attain to.

It is this line of thought that Mr. Kipling has made articulate in his verses "To the True Romance":—

"What is is thine of fair design in thought and craft and deed.
Each stroke aright of toil and fight that was and that shall be,
And hope too high, wherefore we die, had birth and worth in thee."

And again in "L'Envoi"—a celebration of an accomplished work with all the imagery of building operations, beginning:—

"My new cut ashlar takes the light where crimson blank the windows flare;
By my new work before the night, Great Overseer I make my prayer.
If there was good in that I wrought, Thy hand compelled it Master thine;
And where I failed to meet Thy thought, I know through Thee the fault was mine."

That is the way to regard the function of design—as a thing with a right and wrong about it; not a mere matter of taste and whim. Why the very phrase the "Architect of the Universe" makes the paltryness of the vast majority of the architectural performances of the last century appear as sheer blasphemy by contrast.

Well, to return to these same elements, they are:

Firstly, That sympathy born of knowledge, or knowledge born of sympathy, I know not which it is, that enables the designer of a tea spoon or a town hall to realize the full uses of the object he is to conceive. This element is made up of all experience.

Secondly, and of equal importance is a knowledge and sympathy concerning the material and technique (for these things are interdependent) by which the designer's idea will gain tangible concrete existence.

Thirdly, we have scholarships in art which constitutes our heirship to the vast heritage of past traditions, past masterpieces, past failures.

And fourthly, there is the sense of proportion which some men have and most men lack,—this is not a matter of rule or teaching, and the schools of architecture which have professed an exact science of proportion as a thing which can be taught have failed absolutely to leave behind them monuments of any human interest. Cold stones at the best. I refer particularly to the influence of Vitruvius.

It is not to speak of the attainment of knowledge of "what is wanted," nor of scholarship, nor of proportion, that I venture to intrude upon your time, but to discuss very briefly a few examples of the influence of material and technical process on design. In the Ruskinite literature truth is made out to be the touchstone of good architecture, and "Gothic honesty is held up as a moral precept for our architectural regeneration." Now a great deal of the Ruskinite literature, especially with regard to architecture, can only be regarded as charming prose but in thus claiming for truth a place in design from which it had been systematically kept out for a matter of a hundred years, Mr. Ruskin and his followers may be said to have lit the torch which resulted in the revival of sane design in England and which despite the temporary aberrations of the "Art Nouveau" movement is making steady progress all over Europe and in the States.

Now the great quality of truthfulness can only be obtained by having due regard for the natural limitations of materials themselves and the techniques to which they are subjected.

Of course one of the most fertile sources of change and evolution in style has been the translation of forms originated in one material to a second, and a subsequent amelioration of these forms in adapting them to the new material and the changed technique. Not to dwell upon the wooden origin of the Greek orders a few examples from Gothic work will make the point clear.

We have in the 13th and 14th centuries, the evolution of window tracery by gradual stages from groups of detached lights to a highly organized system of window design—and all evolved in stone! In the 14th century we have the miniature reproduction of stone tracery in wood panelling and screen work with certain changes in the forms due to the wood and the joiner's tools being substituted for the stone and the mason's chisel, and a system of framed panelling dominating the design of the whole. Then, later in the 15th century, this system of framed panelling is transferred back to stone wall surfaces and ceiling vaults in the perpendicular style of Gothic. This phenomenon, Mr. Prior in his history of Gothic Art in England refers to as "the discovery of the principle of panelling by which was got a scheme of surface distribution that employed partition horizontally and vertically as a reasonable exposition of space."

Then again the diverse ways man has found to deal with metals or even the same metal have afforded fruitful sources of artistic inspiration. Let us for a moment compare wrought iron and cast iron. We all know that these two things attain different kinds of strength and are formed in different ways. We all also know that wrought iron is continually being copied in cast iron. (See any trade catalogue).—We are also aware of the reason,—cheapness; and the result is a highly fragile and unreliable kind of a railing from the

utilitarian point of view and utterly lifeless, stupid and ugly from the artistic standpoint.

A clumsy, thickset heaviness is right and proper and beautiful in cast iron while a lacelike slimness is equally characteristic of the material and technique of wrought iron. Here I have the cast iron parapets of two bridges in St. Petersburg which as cast iron design leave nothing to be desired and some English XVIICentury wrought iron which shows at its best the full influence of the hammer technique.

BELTON HOUSE, LINCS:
Private Entrance to Churchyard.

Cast Iron Parapet, Nicholas Bridge, St. Petersburg.

One more example, and this from the breakfast table of the average boarding house will show how general is this disease of blatant sham in the field of design.

Look at the ordinary cream jug or sugar basin. It is facetted all over with a design of geometrical structure natural to cut crystal and to nothing else. But is this crystal? and is it cut? I trow not! It is very common glass, it is moulded and the facets are so futile that they absorb more light than they reflect. Why was the sugar basin made so ugly?—for before

Cast Iron Parapet, Alexander Bridge, St. Petersburg.

it was squeezed into its mould it had all the grace and beauty of a ball of glass in the blowing. I suppose because taste is thoroughly depraved and the ordinary man finds a beauty (to him it is beauty) in the imitation of what is rich and rare and a misguided satisfaction in getting the appurtenances of life cheap.

Enough has now been said to prove the contention that materials and techniques have it in them if rightly apprehended to suggest a very great deal with regard to the decorative treatment of objects, and it has incidentally been made abundantly evident that no good results from avowed and unadapted imitation in one material of another or of a superior by an inferior technical process.

In the course we are initiating work of the different building trades will be studied as such regardless of historical sequence, and the masterpieces of all periods will be called in to illustrate the best way of doing things at the time when they were done best.

Designs for details of all the trades will be prepared not as tricky sketches but as working drawings.

By this means I hope the students will get at least a glimpse of the best workmanship of our civilization during the last 3,000 years—XVI Century plaster work and XIV Century glass; VI Century mosaics and XII Century marble inlay; XV Century carving in marble and XIII Century carving in stone. From Italy and England, Constantinople and Rome, France and the Low Countries and sunny Spain.

When the student understands Gothic joinery construction and Renaissance iron work, Modern plastering and Ancient glass painting, there is some profit for him in the study of historical styles and ornament. Without such knowledge such study can only be hurtful to any instinct for design he may possess or which might be induced.

This, gentlemen, is the message as I take it of the Gothic Revival of the 2nd half of the XIX. Century—a movement which by the way has had its chief effect for good in classic design. To treat materials with sympathy and techniques with understanding; to ask what shall this be made of or how will that be wrought before the pencil is committed to the paper; and above all things the negative precept not to sham.

In the burnt district of Baltimore a company is about to install a central heating and refrigerating plant. Prof. Woodbridge is said to be making a study of Washington public buildings for a similar purpose. The use of such a plant should greatly reduce the fire risk and consequently the cost of insurance. It is proposed to install meters which will register the amount of condensation in the pipe lines, so that the consumer will pay for only the amount of steam used.

VENTILATION.

By Robt. Bennett.

Ventilation is a term applied to the method by which a due supply of fresh air is maintained in buildings and other confined places.

The word was invented about 200 years ago by Dr. Desaguliers, a well known scientific man of that time, who devoted a great deal of time and money and skill towards improving the sanitary conditions of buildings, which at that time were considered very bad. He invented a "fanning wheel," or, in other words, an "air propellor," which was worked by manual power, and the man who worked it was called the "ventilator." The word has since been divorced from its original meaning and is now used to signify an opening in a building through which air may, or may not, pass, according to circumstances.

Everybody knows that a supply of fresh air is necessary for all living things, even for plants and vegetation. To cover the head with a cloth for a short time produces a sense of oppression, and on its removal a feeling of relief is experienced. The heat of the person's breath causes oppression. People often say of a crowded building "it is too hot," whereas the discomfort is caused chiefly from the impurity of the atmosphere.

Many diseases are produced by the impurities in the air. Continued breathing of impure air lowers the tone of health. Consumption and scrofula are attributable to vitiated air. The instance of the confinement of 140 Englishmen in the Black Hole of Calcutta in the year 1756 is illustrative of the fatal effects of breathing foul air. After 10 hours of imprisonment therein only 23 persons were found alive. Fresh air is essential as the purifier of disease and also for resisting diseases. The use of gas adds greatly to the impurity of air. The poisonous effect of gas combustion has been the cause of many deaths.

The subject of ventilation is being sadly neglected. Churches, houses, schools and public buildings are being built without proper regard to necessary ventilation. Those responsible for the building of churches and other places of worship seem to be the worst offenders in this respect. For instance, a church is planned and submitted to, and passed by a fixed authority—it is difficult then to introduce changes. The usual form of church building, copying more or less the beautiful architecture of the 13th or 14th centuries is by no means an ideal form from a sanitary point of view, whatever it may be in other respects. It is generally built in the form of a nave and side aisles, lighted by clerestory windows, giving practically (including the chancel) four ceilings of different heighth, making it most difficult to extract the air at the level of the roof. The clerestory windows chill the warm air as it rises, and send it down in the form of a cold draught on to the heads of the congregation. The roof is lofty and dark, necessitating a large amount of light, and as a rule about twice as much gas is burned as is necessary. Nonconformist places of worship are even worse on account of the frequency of galleries and consequent crowding.

How often do we see the windows of a church opened when one or two of the congregation have fainted from the stuffy atmosphere of the buildings. Only recently in a west end church of the city of Toronto I was an eye witness to that sort of thing—the service had only just commenced and everyone apparently felt the discomfort of the badly ventilated place—when two ladies fainted and were taken into the vestry by the wardens—then the windows were opened to admit fresh air. The fresh air came in with a mighty rush which caused a great number of the worshippers to look askance and to draw their garments closer around them, in fact I noticed two gentlemen turn up their coat collars during the prayers; needless to say the service was not so enjoyable in consequence. We often catch severe colds coming out from churches, concert rooms, public buildings, theatres, etc., from that very cause.

Dwelling houses, too, suffer from lack of proper ventilation. It has often been remarked that we are apt to prize but lightly what we possess in abundance, and it is a fact that cannot be denied that the two most important foods on which human life depends, viz., pure air and pure water, are by the great majority of us least esteemed. These two foods, more especially the former, are so abundant that we need pay very little attention to obtain them. We should recognize the importance then of supplying every building and habitual dwelling with proper ventilation. In thousands of houses in our great cities the most elementary principles of ventilation are systematically ignored.

People who would take the greatest care not to drink polluted water, are yet careless of breathing impure air and seem to forget that one may be quite as dangerous as the other—personally I am of opinion that impure air is really more dangerous than impure water, since the air is taken directly into the lungs and comes in contact with the blood more speedily than water which enters the stomach. I do not propose to write with medical authority at all, but simply from a little observation of my own. I believe that ventilation is an exact science, admitting of exact results, and if everybody could be induced to believe the fact that bad air was detrimental to health; if the fact of a room being close or stuffy was regarded as disgraceful; if people refused to attend a badly ventilated place of worship; then the architects, the builders and the occupiers would soon find means to alter the existing state of things.

FERRO CONCRETE CONSTRUCTION.

A lighthouse of ferro-concrete has just been constructed at Nicolaieff, near Odessa. The height is 131 ft., the diameter at the base 28 ft. and that at the top of the shaft 6ft. 7ins. The service-room which is 14ft. 3ins. in diameter, is corbelled out, and thus overhangs 3 ft. 10 ins. on each side of the tower. For purposes of design the tower was considered as a tube firmly fixed at one end and acted upon by a distributed pressure, due to wind, 56·4 lbs. per. sq. ft. The foundation is sunk only 8 ft. 3 in. below the surface of the ground. The skeleton consists generally of upright rods and of circular rings, the surrounding concrete being mixed in the proportion of 660 lbs. of Portland cement, 1 cu. yd. of ballast and half a cubic yard of sharp sand. In order to ensure that the concrete takes a firm hold of the framework the latter is brushed over with grout prior to the concrete being run in. It is claimed that a saving of 40 per cent. is effected by the use of the ferro-concrete. The weight of the building is given as 453 tons, of which 342 tons only represent the weight of the ferro-concrete, whereas the weight of such a light-house put up in the ordinary way would be 1,343 tons.

BY THE WAY.

In consequence of the destruction wrought by recent fires the Norwegian government propose to make compulsory the use of brick in building. Hitherto the decision as regards materials to be employed has rested with the municipal authorities, and wood being plentiful and cheap, has been largely used.

× × ×

As a rule the streets of Chinese cities are badly paved, but one of the coast cities is an exception in this regard. The streets of this city have been paved with grind-stones, i. e., stones originally employed for the grinding of meal, but which, when partially worn out and defective, have been put to this new and useful purpose. They number many thousands and must therefore have been collected throughout a wide district.

× × ×

The plan adopted in Toronto and other Canadian cities of placing a band of brass having an inverted edge round the trunks of shade trees to prevent the tussock moth from climbing to the top and destroying the tree, is in tropical countries applied to the cups of the small iron supporting columns of buildings to prevent destructive insects such as the white ant and all sorts of vermin from climbing beyond them. The flight of steps leading up to buildings in these countries either stand in pans of water or are painted with grease to render them vermin proof.

× × ×

That well-known and usually well-informed journal the English Builder is considerably astray in some of its recently published remarks on cement construction in Canada. It is not the fact that cement coffins are largely in use in Canada, indeed so far as we know they are not manufactured here, nor is the statement that concrete steel construction appears to have made little headway in Canada, much nearer the mark. Contrary to the impression which the editor of the Builder seems to have gained—building methods and materials in Canada are quite as modern as those of the United States.

× × ×

It is very galling at times to have to follow one's own advice or to swallow the medicine prepared for another patient, so no good American can wonder that our newspaper writers are writhing in indignation at the audacity of the Canadian Government in ordering the deportation of certain civil engineers holding important positions in the work of constructing the new Canadian transcontinental railroad, the Grand Trunk Pacific. What right has Canada, or any other country, to protect its citizens by enacting an "alien contract labor law?" Is not that one of our own most precious inventions, and can't we do something to prevent an infringment of our rights in it? One is sometimes tempted to believe that Americans nowadays are a bit too strenuous to be wholly satisfactory occupants of this world.—American Architect.

× × ×

Mr. Robert Williams, F.R.I.B.A., of London, has been commissioned by an Egyption Pasha to prepare plans for a Mosque to be erected for the benefit of the Mohammedans residing in the great metropolis. The plans which are to be submitted at Constantinople for the approval of the Sultan, show a facade 120 feet in length and a longitudinal measurement of 150 feet. The style is Saracenic, or the mediaeval architecture of the Arabs. The building will have a base of polished red granite probably from the old Assouan quarries. The walls will be of red Mansfield stone, relieved with Doulting and Portland stone. The details of the interior will be richly done in marble and Welsh jasper. That part of the floor where the people prostrate themselves will be of teak, and the furniture of oak and teak. The whole building will be surmounted by a beautiful minaret, with balconies and galleries, about 200 feet high. Groups of turrets will also surmount other corners of the mosque, and these will be ornamented with golden spires and crescents.

CEMENT FOR THE NORTHWEST.

In view of the certainty that cement must enter largely into the construction of buildings in the Canadian Northwest, enquiry was recently made of a number of the cement manufacturing companies and wholesale dealers in Eastern Canada regarding the possibility of successfully manufacturing cement in the Northwest. They were asked it they had made any investigation to determine whether the necessary materials for the purpose were available, and if it should be found impracticable to manufacture the material in the west, from what quarter the supply would be likely to come. To these enquiries have come the following replies :

Marl and clay—the two raw materials used in the manufacture of artificial (the best) Portland Cements, are to be found in every province of Canada. Lime stone takes the place of marl where the latter is not found, but is deficient in quantity of carbonate of lime compared with marl or chalk. There is no reason why in the Northwest Portland Cement should not be made profitably. The Canadian Pacific Railway started a factory near Vancouver some years ago on a small scale for their own requirements and ran it successfully as far as the quality of the material turned out was concerned.

D. McNALLY & Co., Montreal.

DEAR SIRS,—Replying to your circular letter of the 22nd inst., would say that at present we consider it ridiculous for anyone to think of promoting any more cement factories in Canada. Even with the North-West market and without the several factories now under construction in Ontario, the Canadian factories have been selling at a loss in order to get rid of their output. After the factories that are now being built are completed in Ontario, we will require the whole of the Dominion as our market if it is to be made a paying industry. We would rather see cement factories in the west than to have foreign cement go there but under existing circumstances, consider it unwise and unprofitable for anyone to build another cement factory in Canada.

THE HANOVER PORTLAND CEMENT CO., LIMITED.
HANOVER, ONT., Sept. 24, 1904.

DEAR SIRS,—Replying to your inquiry we understand from reports that the materials for making Portland Cement exist in some localities in Manitoba, but as to their extent and accessibility, we are not aware. Our own impression is that reports of the political surveys of the several districts would give more accurate information. In the meantime it appears to us that the supply of Portland Cement for the North-West Territories and New Ontario, must come from Ontario and other outside points.

THE COLONIAL PORTLAND CEMENT CO., LIMITED.
WIARTON, ONT., September 24, 1904.

DEAR SIRS,—Replying to your inquiry of the 22nd, I have not heard that the necessary material is available in the Northwest for the manufacture of a high-grade cement, but I do not pretend to have examined the question closely.

C. I. DESOLA.
MONTREAL, 23rd September, 1904.

GENTLEMEN,—Replying to your favor of the 22nd would say that we have not given the question you mention sufficient thought to express an opinion.

THE ONTARIO PORTLAND CEMENT CO., LIMITED.
BRANTFORD, ONT., Sept. 23rd, 1904.

MONTREAL NOTES.

The city of Montreal though not one of the largest cities in the world has yet that cosmopolitan character which is generally found in the largest cities. Perhaps it would be more correct to say that it has that cosmopolitan want of character which belongs to huge masses of humanity moving together and mixing and touching continually yet without any distinct common aim and without even sentiments in common except always on the largest and most broadly human issues. In the city of London, a Chinaman might wander long enough without meeting a single individual with whom he could share, one, even the slightest, of his celestial reflections. But should the same man chance to meet some sudden accident the first dozen passers by would minister to his necessity with as ready and genuine a sympathy as if he also were a son of Father Thames. The further apart we find our lines of life to be cast the more glad we are when we can meet one another on the common ground of simple human nature.

The larger the city the more manifold become the interests of its inhabitants and the more thoroughly disintegrated does sentiment become. In this way such a thing as 'esprit de corps' almost ceases and can only be revived by an appeal to the more elemental bonds of society. Thus cities go on shaping themselves in a shapeless way.

This sort of thing takes place more readily where there are initial conditions tending to keep people apart and in Montreal such a condition exists in the division of the people into French and English sections. The two races are held apart more than anything else by that strange division that a difference of language involves. Everything that tends to freedom in the interchange of ideas and sympathies helps to knit people together and strengthens them in all common thought and effort. Everything on the other hand which clogs this ready interchange must tend either to conflict and friction or to apathy and aloofness.

Another cause of the general lack of common interests in Montreal is the very large influx to the city of persons with purely private interests. They come from many lands each with his axe to grind, and each seeking nothing in Montreal but a grindstone suited to his needs. The rapidity with which the city has grown lately and still continues to grow further contributes to its formless and dishevelled state.

In a city of this kind then, where are we to look for hope for a better state of things—for some pride in having the city to appear well in the sight of men—in the sight of her own men and of the stranger who comes to her gates? The said stranger if he comes by water is tipped out into an unassorted lot of fragments of wharfs and grain elevators. Regretting that he should have arrived at so unfortunate a time when such extensive alterations were just at their thickest, he mounts a cab and is conducted up St. Francis Xavier or St. John street. These curious streets are unfortunately also a little out of repair and if the picturesque profusion of poles and wires were a little less thick one might be able to say whether or not these large buildings were of substantial construction. In St. James street he can recognize that the buildings are indeed substantial and tall enough to satisfy any mind not smitten with the fever of giantism. This street is unfortunately narrow—a result doubtless due to its antiquity—so, paying due reverence to age, he can admire the picturesqueness of this street with its spasmodic buildings. In Craig street one encounters the phenomenon of a fine wide thoroughfare, convenient and central, which is as yet little taken advantage of for trade or business purposes and is largely occupied by a class which exhibits a painfully low order of intelligence in disfiguring whole rows of the neatest old stone houses imaginable with disproportioned and unattractive, not to say repulsive signs, in apparently some kind of simple and unquestioning faith that they thereby recommend themselves to the general public. A little modesty and tidiness would make a wonderful transformation here.

Telegraph poles and wires we know are mortal and will pass away—we hope to live long enough to see them decently interred underground. The electric car wires give promise of a longer period of pernicious life, but to improved methods of traction these too will yield. These are accompaniments of unperfected engineering devices. They are the derricks and scaffolding required in the growth of our civilization and will be taken down when the constructed fabric comes into the full exercise of its functions with implements more efficient and more seemly. But these disfiguring signs are worse than sins, they are blunders, and to architects they are particularly offensive as being a cheap way of obliterating even the finest architecture.

What one should wish and can surely hope to see is an intelligent emulation in excellence of appearance, not in magnitude of announcement—in appropriateness and charm of expression not in loudness and piercing quality of voice. At the present day advertisement is everywhere loudly acclaimed as the one true god who will lead our endeavours to success. Let us remember then that our gods are images of ourselves and be careful how we shape our advertisements.

In the beautifying and ennobling then of this our so cosmopolitan and formless Montreal we must look to the broad sentiments which are the property of all mankind. Its diverse elements are a great potential mine of wealth. Though hard to fuse together their eventual fusion will yield the richer product. The resultant character will be broad and inclusive, made up of many of the strands that compose our human nature. Such a character we may hope some day to see expressed in the streets of our city—its buildings with grace fulfilling their functions and therefore looking appropriate thereto, and the people exhibiting manners as sane and delightful as their buildings—both equally free from the present blatant advertisement and untidy scuffling—their work a pleasure to themselves and to those who deal with them.

"CONCORDIA SALUS."

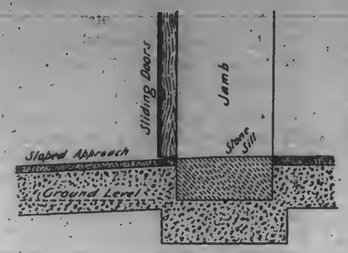
CHURCH HEATING AND VENTILATION.

Particulars are given by the Decorators' Gazette of an interesting method of church warming and ventilating introduced by a German heating engineer in a Berlin memorial church that in general plan resembles St. Paul's Cathedral in London, though of smaller dimensions, the height of the nave and transepts being 82 feet and of the dome 237 feet. The corresponding measurements of St. Paul's are 100 feet and 360 feet respectively. To the height of 80 feet from the floor the walls are traversed by hot-air chambers, so that from the ground to the galleries 22 feet above, there is no perceptible difference of temperature, the air being kept constantly at 60 degrees. The radiating surface is placed high up, in the neighborhood of cooling surfaces, maintaining a higher temperature in the upper portion of the building, and intercepting and reheating the cooled air in its descent toward the lower part occupied by the congregation. There are thus four strata of air of different temperatures. On the ground floor and in the galleries there are very few coils, but along the first entablature, at a height of 95 feet, the coils are sufficiently numerous to counteract the loss of heat through the walls, which are no longer traversed by hot-air channels, and to maintain from this level to that of the second entablature—at a height of 145 feet, or 50 feet above the first—a temperature a few degrees higher than that in the parts below. Other coils are fixed above the second entablature and in the lantern of the dome. To avoid the dangerously chilling draughts that would follow the opening of the doors in the intense cold of a Prussian winter, the entrances are provided with double swing doors and coils are placed in the intervening passage. The engineer maintains that the system of heating the upper more than the lower regions of the air is the only proper course in such lofty buildings as churches. He holds that with the ordinary method the air heated on or below the ground level is cooled in reaching the roof, and, fouled by the products of respiration, descends on the heads of the congregation, unless withdrawn by some such exhausting arrangement as is carried out in the English Houses of Parliament; while in his system the fresh air is warmed to an agreeable temperature in its passage through the walls, and its ascent is favored by the coils between the first and second entablatures. The coils in the dome, although they do not contribute to the warming of the parts occupied by the worshippers, serve effectually to prevent the descent of the foul air by securing its continued ascent toward and escape through the apertures in the lantern that crowns the edifice.—Decorators' Gazette.

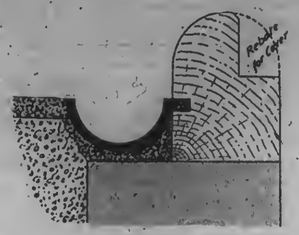
In the construction of a large factory on the site of what was formely the bed of a canal, of Cincinnati, it was found impossible to set a foundation except by driving piles. As wooden piles would rot, resort was had to concrete piles which were successfully driven home by the impact of a 4,000 lb. hammer. The top of the piles were prevented from chipping by the use of a steel bonnet. In some instances it required 400 drops of the huge hammer to sink the pile. This is said to be the first time the this method has been employed in the United States.

SOME NOTES ON MOTOR HOUSES.

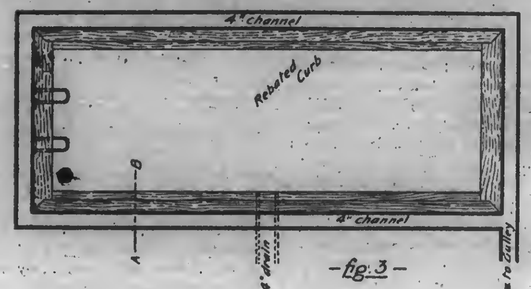
With the swift strides made in the automobile industry during the last few years the demand has arisen for a class of building unthought-of a decade ago; and there will soon be but few architects in general practice who will not at one time or another have been called upon to prepare plans and specifications for a motor house. At this early stage no settled definite planning has been arrived at; much that has been done must be looked upon as merely tentative; and I would therefore ask the reader to remember that I put nothing forward as final, preferring my remarks to be treated simply in the light of suggestions, from which (in combination with the opinions and experience of others) some settled lines may in due course be evolved.



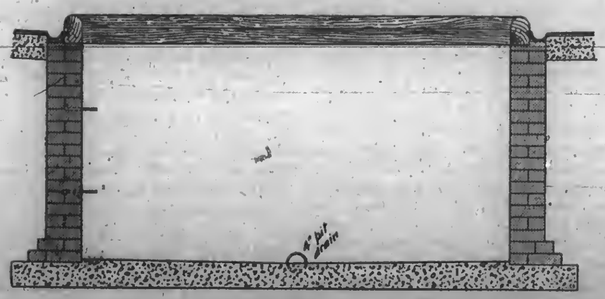
—fig. 1—



—fig. 2—



—fig. 3—



—fig. 4— Scale of Feet —

It is scarcely necessary to say that nothing of a temporary nature should be deemed good enough for the stabling of a motor car. Wood and corrugated iron buildings, whether portable or fixed, are both unsuitable for the purpose, warmth, dryness and approximate equality of temperature being of first importance in the preservation of a car. It is a poor policy to risk the well-being of a vehicle costing hundreds in order to save a few pounds on the structure in which it is to be housed, and beyond this there is the question of personal safety, which may be seriously imperilled in consequence of the rusting of parts of the machinery or the action of damp upon the fabric of outer covers and the rubber of inner tubes.

With the style of building I have no concern, that being entirely a matter for the individual architect neither am I concerned with the materials to be employed for walls and roofs so long as they are lasting and thoroughly wind, weather and damp-proof. The walls internally may be finished with struck-jointed brickwork or they may be plastered; but the best finish is of course given by some form of tiling, with a dado of enamelled bricks for the harder wear in the lower portions of the walls. Roofs should be boarded and felted and should, if possible have neither rooms nor loft above so that plenty of top light may be obtainable.

In place of the obsolete coach-house doors, steel-hinged wood revolving-shutters or sliding doors should form the entrance, as with these there is no danger of damaging the car by the swinging of a hung door in a heavy wind. The doors, if sliding, must run on an overhead track, and all framing should be inside, with flush boarding outside to throw off the wet. A paved approach laid to an easy fall leads to the stone entrance sill, which is on the level of the finished floor surface and about six inches above the level of the surrounding ground (see Fig. 1).

The chief figure which distinguishes the motor house from every other building is the planning of the floor, and it is in regard to this that great care must be exercised. Whatever the size of car to be housed, a pit must be provided for cleaning and inspection purposes, and it is advisable (though not necessary) in the case of a double motor house to have two pits, one for each car, so as to avoid the frequent changing of position which would otherwise be necessary. I will, however, confine myself to a single pit. This should be not less than 3ft. wide and 4ft. 6in. deep (see Figs. 3 and 4). Length will depend upon the size of car; but it would be as well to anticipate a little and make it, say, from 9 to 12 feet—the latter size being, in my opinion, the maximum requirement for any make of private car. The pit may be brick built with rendered faces, and with floor finished as the floor of the house, and no care or expense should be spared to render it thoroughly watertight. The drain will discharge outside over a trapped gully, with small inspection pit built up, or an ordinary syphon-pipe with extra inlet carried to ground level (to form inspection eye) may satisfy local requirements. Around the pit is laid a 7in. by 5in. hardwood curb, securely fixed to the brickwork of the walls, the curbs laid in the direction of the length of the pit being rebated to receive the movable covers (see Fig. 2). The curbing should be laid so as to be 4in. above ground level, as otherwise (i.e., with a flush or nearly flush curb) there is a danger of the car mounting the curb and sustaining serious damage by a fall into the pit. Pit-covers are best made in small light sections, so as to be easily moved, and they must be strongly framed (to take the weight of the heaviest car) and provided with flush handles for lifting. Personally, I do not see the need for a cover at all; but owners seem to like them, and after all it is a matter of small moment. Step irons should be built into the brickwork of the pit for access purposes.

The floor itself may be formed of any non-slippery, impervious and hard-wearing material—asphalt or tiles for preference. Around the pit a 4in. glazed stoneware channel is laid flush with the floor and butting against the wood curbs (Fig. 2), and the floor is best made to fall in every direction to these channel pipes, which discharge eventually in the open over a trapped gulley. With raised kerb and the channels no trouble can arise from water finding its way into the pit.

Lighting and heating are matters which require more or less special consideration in each case. I have mentioned the importance of plenty of light; in fact, the simplest way is to "pier" the walls and fill in with solid frames and casements, having small top lights to open for ventilation in addition to the casement sashes themselves, which may all be stayed open in favorable weather. The roof-lantern will afford constant ventilation in practically all weathers. Heating is a necessity, whether by hot-water pipes, radiators or open fires—the selection being left to the judgment of the architect, upon a consideration of the most suitable system. The life of a car (and especially of its working parts) is very much prolonged by housing it in a warm, dry, equable atmosphere. Artificial lighting is another matter which must be regulated by local facilities; to discuss it here would be a waste of space.

Lavatory and water-closet should both be provided, together with a wardrobe for motor garments, rugs, etc., and a drying-room—fitted with pegs, battens and slatted shelves—for the reception of the same after a wet run. The drying-room will need to be well ventilated for the escape of moisture, the heating arrangements depending upon those adopted for heating the motor house. A small workshop is a very handy thing to have in connection with the house; but where expense precludes the provision of this a bench (fitted with vice, &c.) should be fixed in one corner of the house, and racks provided with tools, spanners, wrenches, &c. Wooden harness pegs are eminently adapted for spare covers, and a row of these should be placed in some convenient position. Water must, of course, be laid on, and it is a wise plan to have the taps fitted with unions for hose connection. Petrol is best stored with other oils in a separate building (of however rough a nature), detached if possible.

As to the size of the motor house itself, this will again naturally depend upon the size of the car, but ample room must be left to get round on all sides. Excluding the space required for bench, cupboard, lavatory, &c., a safe size for a small car is 10ft. by 14ft., and from this one may go, in the case of larger cars, up to 14ft. by 20ft. It is the biggest mistake in the world to cramp the building, as an extra foot or two by no means entails a proportionate initial cost, whereas structural alterations for the accommodation of a larger car may mean a heavy expenditure.—B. WYAND in London Builders' Journal.

CHAINS USED IN BUILDINC CONSTRUCTION.

St. Paul's Cathedral, with its celebrated dome, higher outside than inside, was completed by Sir Christopher Wren about two hundred years ago, and he put an iron chain round the base of the cone. The construction of the wooden external dome, the support of the stone lantern by an inner cone of brick-work, quite independent of either the external or internal dome, are wonderful examples of Wren's constructive ingenuity.

In the "Parentalia," written by Wren's grandson Stephen, partly in his own words, partly in those of his grandfather, is this passage: "Although the dome wants not butment, yet for greater caution it is hooped with iron in this manner; a channel is cut in the bandage of Portland stone, in which is a double chain of iron strongly linked together at every 10 ft., and the whole channel filled up with lead."

DESIGN AND CRAFTSMANSHIP.

Ever since the ideas of mankind had to be converted into concrete form, there has existed a gulf more or less wide to bridge over, and even in this twentieth century, with all its arts and appliances, we are still scarcely able to reconcile design and construction. The exhibition of selected works from the various national schools of art we noticed last week shows to what an extent this discordance is still observable. The examiners in their several reports speak with much reserve and caution of works in different branches which indicate this separation. Though in many instances the drawings or designs reach the standard required, the executed specimens sent in show a falling-off; the designers' ideas have not been realized in some important quality. In not a few cases the subjects attempted are beyond the students' capacity or powers as with regard to the architectural designs. In many more the design has been made in complete ignorance or forgetfulness of the actual condition and limitations of the material; and directly the student passes the barrier, puts his ideas into execution, he finds a great deal of the beauty and glamour of the conception disappear. These qualities seem to elude his grasp, and in their place we get the hard and intractable qualities of stone, wood, or iron, the want of precision and definition inseparable from moulded and cast materials, and machine tools, the inequalities of form and colour caused by firing in pottery and tiles, and the technical defects inherent in textile and woven fabrics. A decorative design may look admirable on paper; but when it comes to be translated into the real material, by stenciling or brushwork, by the arrangement of tiles or tesserae or thread, the effect may have been considerably diminished. We notice these defects in most of the stencilled work we see executed, in tile decoration, where the painting and pattern are at variance, and in woven textiles where the technique of weaving is not understood. In furniture, wood inlays for panels, we observe a distinct inferiority in the executed work if the designer has not selected the proper-coloured wood for inlay, or placed them according to their grain to suggest the nature of the object presented. In the very artistic firescreen we noticed last week by a student of the West Ham School for which a gold medal is given, the designer has observed these points, he has selected suitable coloured woods for the figures representing the four seasons, and the grain and "figure" of these woods are made to suggest the drapery or vestments, the hair, even the growth of trees in the background. The designs on paper are sometimes at fault: they show or expect too much; they suggest ornament and treatments which cannot be realized in the particular material; they are frequently overcrowded with ornament. On the other hand, the designer may know little of the material he uses or the method of construction; his selection of material to represent his design may be imperfect, or his method of application faulty. Owing to one or the other of these errors, or both, the execution fails. One sometimes sees a design that is really defective and faulty in itself, yet which by the skill of the workman or artist engaged in execution is produced in a very satisfactory manner. This result is because the craftsman has discerned the designer's intentions, and has put forth his own personal skill in the execution. It is the way in which the success and charm of a good deal of Mediaeval building and detail can be explained. Both designer and craftsman devoted their heart and soul to the work: they put into it their best efforts, and what one failed to do the other rectified or perfected. But under our modern system of workmanship we have no such corrective: the designer does not co-operate with the executive artist—there is little sympathy between them, and so the inferior design is misinterpreted or aggravated in the result. The craftsman obtains no personal interest in the work or extra pay for endeavouring to improve the design or offering suggestions. Why should he trouble to do more than follow the drawing when he reaps no reward for his skill? So the modern estrangement between the work of designer and craftsman is detrimental. On the other side, the design may be all that can be desired; but it is placed in the hands of workmen or artists who are imperfectly educated in art, and who do their work in a mechanical way. This is, perhaps, the commoner failing; it is the one which the architect who carries out contract work so often experiences. His ideas and intentions are thoroughly misunderstood or evaded, with the object of cheapening cost. Such things occur as details altered or cut down, mouldings misunderstood or altered, depth of relief diminished, the ornament mutilated—in short, the design really "murdered." Whichever may be in fault—the design or the material and method employed—the result is disastrous for art. The two things must go together. Design and construction or handicrafts engaged must be linked together, as any disagreement or difference is fatal to both. We may have good construction without skilful design. Thus we may have a building perfect in every trade, and scientific in its construction; but from error in planning or a discord in the external design it never satisfies. Or we may have the reverse—perfect design linked to a building that is badly constructed, and is always showing signs of weakness and decay. Neither is desirable. The Schools of Art combined with technical instruction have attempted to bridge the chasm—to unite both the artist with the industrial producer. We do not deny a good deal has been done in this direction. Artists and designers have been brought into touch with manufacturers. We have now much better and more satisfactory metalwork, woodwork designs, furniture, pottery and porcelain, stained glass, modelled work, wallpapers, hangings, carpets, and textile goods, and the training in art has influenced our industries all round; but still there is the distinct and separate training given to each. The designer is still taught to furnish designs based on traditional methods apart from materials and methods of construction, and the craftsman is taught little of the art or methods employed, and is satisfied if he can turn out so much work in a certain time. Other causes have kept the two apart.

The divergence between design and construction or execution is greater under some conditions. Where the artist designs in only one material, the difference is less than it would be if several materials are employed. Thus designs for modelled work are more likely to honestly express the actual result; but when several materials have to be taken into account in the construction, there is the likelihood that the design cannot express equally well in each the actual want. A work of architecture comes under this category. A building is constructed of various materials; brick, terracotta, stone, timber, iron, plaster, &c. It is almost unreasonable to expect the architect to be expert as a designer in each. If he can express his intentions artistically in brick or stone, we may excuse his faulty details in materials like iron or wood or plaster. The result is that in building the power or ability to design is much more rare; it requires more extended study of materials and trades than the designer in wood or metal, or any other single material. The artist in one material soon acquires a manipulative power over it: he knows its structure and physical peculiarities, and he soon acquires the skill to handle it and to bring out its technical and artistic qualities. Thus in modelled design, in metal or repoussee-work, in tilework and pottery, the results are more satisfactory: a shorter study is necessary in mastering the technical methods, and the designer, in short, is able to express his ideas more directly in the material. So the designer and worker in modelled work or metalwork or carving ought to be the same individual; in the old days they were always so, and it is almost impossible to imagine a designer of sculpture or carving who was not also the sculptor or carver. So in other art-crafts where only one material is employed, like those of wood, or metal or plaster. The most satisfactory results are derived when the two functions of designer and handicraftsman are united. The students' work done in the London County Council Central School of Arts and Crafts is an effort in this direction, the aim being to supply those engaged in artistic handicrafts, training in design and manipulation which is now impossible owing to the subdivision of labour and modern mechanical processes. The modern workshop has not yet assisted in this direction, though to it we must look for new spirit and energy. In architecture the relations between design and craftmanship are more complex. Several materials have to produce the result, requiring a band of trained craftsmen under one head. And the more composite the building is, the greater is the effort required for a satisfactory result. Thus in buildings in which the effect is largely due to one material, say, stone or brick, more unity and harmony of effect is attainable than in a structure composed of various materials, each having its own limitations and methods of execution. Thus it is that in the designs contributed for buildings there is a larger number of failures than for designs in one material. In this connection the question of the architect being capable of executing his own designs (if possible) comes in. There are many who protest, and of course, the "professional" architect is chiefly averse to such an idea. It is, of course, nowadays at least, quite impossible to imagine any such a union as architect and craftsman, although it is obvious it is all the better for the designer to have an acquaintance with the conditions and limitations of the work he is designing. But, as we have hinted, he would have to be a craftsman in each of the materials employed in a building—an impossible thing nowadays at least. Imagine a Scott, a Street, or an Aston Webb so engaged. As Mr. Walter Crane has put it, an architect would not be able to pay his rent and taxes if he did so; yet, he observes, with some force, "If a designer does not realize the conditions of his design and the nature of the method, and the materials by which it is to be carried out, he cannot practically design at all." We will not discuss the point now, or how far such a combination as an architect and craftsman is possible; but it will be admitted that designers have imparted some freshness into crafts that had sunk deep into trade ruts. It may be an ideal, but not a practical mode of working. Designers of buildings and decorators must now intrust a great deal of their work to trained assistants—such, for example, as the repetition of a pattern like a scroll or ornament, or the details of woodwork or ironwork. It would be wasteful of his time and energy for an architect to have to execute or even supervise every detail of a building. The workshop system is one way by which the difficulty can be solved—that is, a designer co-operating with assistants or craftsmen whom he can train and inspire, and from which band of workers others may learn the craft. As one writer says, every designer should be able to take up the craft for which he is best adapted. There are some crafts which depend more on individual expression (as those of one material) than others. These are best in the hands of men who can design as well as execute in them.

Our leading artists and designers now look to the workshop and the studio as the main sources of inspiration. Mr. Ashbee has remarked that art must be carried on in the workshop and not in the studio, and he draws a graphic picture between the workshop and the studio. The latter is described as a "Happily situated nest somewhere in the region of villas and top hats; it is fitted with all apparatus for the lighting, lifting, and wheeling to and from exhibitions of the large masterpiece, and it is ornamented with all the conventional gusto of the prevalent Queen-Anne-ity. Within these are scraps of damask silk, bartered from Roman curiosity-shops, divers subjects under way, various Madonnas of the future, suggestions of decorative work sprayed upon the odd moments of panels. There is a cast from studies, a photogramme of Millet, a skeleton, and a lay figure. In the corner a pair of embroidered slippers. . . . The inmate for whom these things have their being works hard, appreciates the solitude and silence of his surroundings, and is comfortably conscious of his Bohemianism. In the afternoon there are lady visitors, and his servant brings in five-o'clock tea." The workshop is almost as light as the studio, though less pleasantly situated, and near the racket of some big thoroughfare. But what matters noise? There is noise within—hammering and sawing and what not. Nor are the internal surroundings as pleasant to look on. Blue whitewash takes the place of damask fragments, and movable gas-jets of patent reflectors. The place is in a condition in which no housewife would enter it, and the gluepot is simmering on the stovepipe. As to the fittings, there are benches and racks for the tools and a good deal of grime. To hang up prints would be inadvisable . . . . The inmates of the workshop pursue their avocation with the regularity of clockwork; a light in their faces, perhaps of an armed resistance to something—and the dinner-hour at twelve o'clock is enlivened with the perusal and discussion of racy paragraphs from the half-penny radical prints. These are the two pictures; but I hold that in the higher sense the proper place of decorative art is the latter." And the same writer goes on to say: "In the first place, the right understanding of forms of ornament—elements of design—is only possible in their direct bearing on forms of material—elements of construction. You need your basis of matter wherein to engender the spirit. You must understand the stone, the wood, the pigments, the clay; what each can do, what its limitations are; and this means an understanding—if merely for the sake of conceiving our

own incapacity to use them—of the tools that are the guardians of these limitations. 'Rivington's,' that famous tome of building construction, whose pyramidal ascent of facts has to be scaled before youthful architects pass Royal Institute examinations, would lose half its value if it were not for the fact of the isolation of the architect's studio, euphemistically termed his office; but a half-hour in the workshop would save days of fruitless drudgery over its pages." As he says, every hour in the workshop reveals something, or we may go to our studios and copy realistically; but, given the knack, it always remains easier to copy realistically than to master the limitations of material. It is true also that ideas may be conceived in solitude, but they are brought to birth by co-operation. By coming together creativeness is engendered by the very magnetic affinities that spring up between men.

Academies and exhibitions—the agencies of modern times—have had a blighting influence on practical art by encouraging the sensational and unreal. In the old days, the artists of the Italian, German, and Flemish schools produced handicrafts in abundance. As Mr. Yeames, R.A., said some time ago, referring to the drawbacks to art arising from competitions and exhibitions: "Then the artist kept a shop, and priest or noble who wished his church or palace decorated went to his shop, and, if satisfied with his skill and pleased with his designs, commissioned him to decorate a chapel in his church or a portion of his palace. The artist's thought was then to bring his work—whether fresco or carved marble, whether Scriptural subject or fountain with Venus and Tritons—well into harmony with the surroundings of the place which it was henceforth to occupy, and to make it express not only his own fancies and views on art, but also the feelings and character of the man who gave him the order." Nothing sensational was attempted; there was a community of thought between the designer, the patron, and the craftsman. All concerned worked in unison: there was a harmony between building and ornament, between sculpture and painting, between furniture and vestments. The point chiefly to notice is that exhibitions encourage and foster the unreal and tricky effects of art and draughtmanship, to the detriment of workmanship, material, and texture. In this manner they discourage the practical side of art work. The only corrective to this unreal quality of design is to look at it from the workshop point of view. Under such a system there would be a living tradition in design and workmanship. To the separation of brains and hands we must attribute the present paralysis of art. No one can be so unreasonable as to suppose that there must be no subdivision of labour: the workshop system assumes such a system where designers and craftsmen can learn each from the other, and where there is a helpful co-operation in the carrying out of a building or a piece of decoration. Technical schools are doing something to train designers to execute their own designs in at least some materials.—The Building News.

The joint weekly luncheons of the Toronto Chapter of the Ontario Association of Architects and of the Toronto Eegineers' Club have been resumed. They are held in the rooms of the Societies, 94 King Street West, every Tuesday at one o'clock. A cordial invitation is extended to all engineers and architects to attend.

ARCHITECTURAL CLASSES.

The Mathematical Classes for architectural students conducted by Mr. A. H. Harkness, B.A., last autumn and winter, were resumed in the rooms of the Ontario Association of Architects, 96 King Street west, Toronto, on the evening of Monday, October 10th. Arrangements are being made for a continuance of the studio classes, but announcement has not yet been made of the date on which they will be resumed. These classes as heretofore will be conducted under the auspices of the joint committee of The Ontario Association of Architects and the Toronto Architectural Eighteen Club. The usual fee of $5.00 covering tuition in both courses will be charged. An invitation is extended to all architectural students and draughtsmen to join.

COLOGNE CATHEDRAL.

The present site of one of the finest specimens of gothic architecture in Europe was formerly occupied by a cathedral commenced by Hildebrand, Metropolitan of Cologne, early in the ninth century. Some years later, in common with other churches on the lower Rhine, it was practically demolished by the Normans, and was rebuilt under Williebert, and after twice escaping destruction by fire in the eleventh and twelfth centuries was burnt down in a great conflagration which occurred in 1248.

Soon afterwards the present cathedral was commenced by Conrad of Hochstaden, the design being attributed to Gerhard von Rile, and by 1322 the choir was completed and consecrated. Subsequently the work preceeded but slowly, especially after Conrad's death. At the time of the Reformation the work was suspended, and after passing through various vicissitudes, the repairing of the Cathedral was taken in hand early in the nineteenth century, and the building of such portions necessary for the completion of the whole structure.

The Cathedral is cruciform in plan, and is composed of a nave flanked by double aisles, and transept with single aisles; the outer aisles terminate at the choir, which is surrounded by numerous chapels. The many richly coloured windows add greatly to the imposing effect of the interior.

NOTES.

Experiments have recently been made in Germany to determine the cohesive power of clay, and, if possible, to increase this power in the natural material. Samples of clay mixed with a two per cent. solution of starch, dextrin and tannic acid were stored for six months side by side with samples mixed only with water. The tensile strength was determined in each case after three week's storage and again at the end of six months. Taking the ordinary tensile strength as one, that of the wet clay was found, after three week's storage, to be 1.35, and after six month's storage to be 1.39. Starch and dextrin did not appreciably increase the tensile strength, but tannic acid gave most satisfactory results, showing the tensile strength during the first three weeks to be 1.75 and at the end of six months 3.22.

Two Canadian patents for fireproof construction have recently been granted. The main feature of one is a network of wires or rods, fastened with hooks to supporting beams, and covered with a reticulated material; concrete is then placed on top of the beams, rods and this material, and above that are placed alternate layers of felt paper and insulating material, and the floor is laid on top of them. The other patent consists of a fireproof tower containing ventilating shafts, in connection with a system of water-pipes arranged in the ventilating shafts and within recesses in the floor of the building. Other inventions are a device for removing shingles and a tiled flooring.

NORTHWEST NOTES

Branch Office of THE CANADIAN ARCHITECT AND BUILDER,
720-721 Union Bank Building, WINNIPEG, October 14, 1904.

The unchangeable wet weather of the past month has greatly hindered the work of finishing buildings in the city and all classes of work are behind hand in consequence. As the cold weather is approaching, contractors are doing their utmost to complete the many buildings on hand, and every endeavor is being made to get all outside work finished before the winter sets in.

Last fall quite a number of buildings were continued far into the winter, but the expense of supplying the necessary heat when bricks and mortar have to be kept hot to prevent them from freezing, and the additional time required for work on account of the intense cold makes it almost a prohibitory proceeding. We understand, however, that rather than carry some of the buildings under progress over until next spring, that they will be continued through the winter, providing sufficient materials are to hand. This in the winter is very difficult to provide for. Here again the question of transportatioo comes in, as freight moves more slowly in winter than in summer.

There are quite a number of interesting structures under construction. The new Free Press building on Portage avenue and Garry street is well advanced and about ready for roofing. It is of steel frame construction with concrete floors and consists of four stories and a basement. The frontage is 42 feet on Portage avenue by 150 feet on Garry street. The outside is of Tyndall stone to the ground floor, Lac du-Bonnett pressed brick and stone trimmings for the upper stories, finishing with a copper cornice. The building is to be of the most modern fire-resisting construction, having iron and slate stairs. The interior is finished in oak on the ground floor and in ash above. It is equipped with the Wabash system of heating and is supplied with its own electric plant for lighting, operating the presses, etc. It will be the most up-to-date newspaper building in the Dominion, having some 40,000 square feet of area. The cost will be about $175,000. Mr. H. Stone, of Montreal and Winnipeg, is the architect. Messrs. H. R. Ives & Co., of Montreal, have the contract for the iron stairs.

The Manitoba Club is another fine building, on which work will be continued throughout the winter with the object of reaching completion in the spring. It occupies a very suitable position on the corner of Broadway and Fort streets. The plans show two wings, but at present the east wing will be omitted and added in the future. The building is being constructed of red sand mould brick and Bedford limestone and will have a frontage of 96 feet on Broadway and 82 feet on Fort street. The first and second stories are for club purposes and the attic and basement for attendants' quarters. Separate suites of rooms will be provided in which the ladies can give private parties. For these there will also be a private entrance. There will be a large lawn at the rear of the block on the south side. This again is adjacent to the old Fort Garry Park, where the old fort gate is keep in good repair as a memento of by-gone days; so that the Club House will always have a large open space at the rear. The building alone will cost $80,000; it is to be richly finished and decorated. T. F. & W. A. Peters are the architects.

Another large building that is nearing completion for the present is the warehouse of Messrs. Teese & Peerse. I say "for the present" as it is the intention to put an addition to it next year. The portion now being finished is 60 x 66 ft., five storeys and basement, but when the whole building is completed it will be 240 ft. long by 66 ft. wide. It is of mill construction and designed to carry 600 lbs. to the square foot, live load. All windows are fire-proof, made of galvanized iron and wire glass. It has a private siding, being built on the C.P.R. track at the corner of Princess street. The present work will cost about $25,000 and after the addition is built it will cost about $100,000. H. Stone, of Montreal and Winnipeg, is the architect, Plaxton & Co. are doing the heating, Cotter Bros. the plumbing and J. A. Payne the painting, all of Winnipeg.

J. H. Hough is building a large warehouse on Princess street which will be occupied by the Alaska Feather and Down Co., Limited. It will be 66 x 117 ft., 3 storeys high with basement, with two additional storeys to be added later, and will cost about $25,000. Darling, Pearson & Over, of Toronto and Winnipeg, are the architects.

Darling, Pearson & Over are also the architects for the new Post-office to be built on Portage Avenue next to the Free Press building. It will be one of the finest buildings in the city. Tenders are to be in by October 17th, but only the foundation will be done this fall.

Several other large blocks will soon be occupied by the tenants. Bullman Bros'. seven-storey building on the corner of Bannatyne Ave. and Albert St. will be occupied as offices.

Another large stone and brick block 130 x 44 ft. is almost completed. It is on Portage Ave., is three storeys and arranged for stores and offices.

The Macdonald & Wright Block, also on Portage Ave., is about ready for the tenants. It is built of local brick and stone and is three stories; also intended for stores, offices and residences.

Messrs. A. Carruthers, Bros & Co. are just completing their building on Logan Ave.; it is 125 x 66 ft. and has three floors.

H. S. Wilson has a large block 105 x 45 ft. on the corner of McDermott Ave. and Albert St. almost finished. It also is for stores and offices.

There are numerous other large business blocks that are being finished of which mention may be made later.

The past season has seen considerable progress in the direction of providing apartment blocks for Winnipeg, something that was very much needed. Although quite a number are being built still the demand has not been met as is evident by the large number of applications for suites of rooms, in spite of the fact that rents are very high. A very substantial apartment block built of brick and stone on Cumberland Ave. will soon be ready for occupation. It is very well arranged in three floors, steam heated, electric light and every modern convenience. Each floor has two suites complete in every detail. Another block of a similar class is being built on Notre Dame Ave., also a large one three stories high on Fort St., one on Main St. in the north part of the city, and another just commenced on Smith St. near Portage Ave.. One would think the demand for offices and apartments would be well supplied by the end of this year, yet one builder tells me he has had at least forty applications for a suite of rooms in his block and it only contains four suites.

Up to the present time there have been 1,552 building permits issued, covering 2,017 buildings, at an aggregate cost of $8,536,700. This is $3,300,450 above the amount of last year up to the same date. Winnipeg has something to be proud of in the fact that no other city on the continent can reach her in this years building valuation. New York comes second and Chicago a poor third while others follow on down the list.

Since writing these notes we regret to say that Bullman Bros.' fine new block previously mentioned has been completely burned, also J. H. Ashdown's large retail store, just opposite, which had recently undergone considerable alterations and improvements, was completely gutted.

We regret to say that Mr. V. W. Horwood, architect, whose plans were accepted for the Public school at Fort William, is in Winnipeg hospital very low with typhoid. His brother, E. L. Horwood, architect, of Ottawa, is attending to the detail plans.

A large block 132 x 130 feet is being commenced on the south-east corner of Portage avenue and Donald street, just opposite the T. Eaton block. Mr. J. A. M. Aikens is having it built and will fit it up to suit tenants. Mr. Woodman is the architect.

The Dominion Express Company's new stables on Alexander avenue east, have just been opened. They are of modern fire-resisting construction. The present capacity is for 25 horses and rigs. Mr. Woodman is also the architect for this building.

Sproats, Rolph & Chrysler are the architects for C. H. Campbell's new house. The tenders were let for $18,500.

The large addition to the Winnipeg Electric Street Railway will soon be completed; further particulars of which will be mentioned later.

The C.P.R. subway will be ready for opening by November 1st and next month we may be able to give a description of the work. The new station, offices, Immigration buildings, etc., are making rapid progress and are being rushed as rapidly as possible, as the present state of things causes great inconvenience to all concerned.

The Canadian Northern Railway are also building a new station at Carberry. It will be up-to-date and will cost about $6,000. Mr. N. H. Fraser, contractor, has the work in hand.

Summing up the situation in the building trade we find all the contractors in a fairly satisfactory condition regarding the buildings they have on hand. Here and there a building has been delayed for want of material, and bad weather has hindered building. Unusual quantities of rain have in cases caused trouble with the excavating and the foundation work, but on the whole nearly all buildings will be in good shape when winter sets in. Inside finishing work can thus be done during the winter. The towns throughout the province are in the same condition; all building is well in hand for the winter.

To say that the contractors have had a busy season is putting it mildly, as most of them have had so much on hand that they hardly know what to do first. Architects are very well satisfied and have plenty of work ahead of them to get into shape for next spring.

DIFFICULTIES AND METHODS OF PLASTERING IN WINTER.

Plastering in winter is always attended with more or less unsatisfactory results. The walls possibly do not become hard or they are disfigured by yellow stains or smoked a dark gray color from the fires used to keep the house warm, or there is an unusual amount of cracking; the white or finish coat rubs off like whitewash or most of the plaster peels from the walls, requiring it to be entirely replaced. These and many other defects are due to very simple causes, which with little care can be easily remedied. So little attention has been paid to the question that the causes of the ill results in winter plastering are little understood.

Heretofore wall plaster has been a mixture of varying proportions of slaked lime, sand and hair made at the building, usually out in the open with no protection from the elements. If cold weather came on the mixture would freeze and could not be used until thawed out, with consequent injury to the binding qualities of the material; or, as often happens, the frozen mixture is applied to the walls to soon come off as the frost thaws out. Then, too, the quality of lime used varies greatly, and poor lime is cheap. Sand also differs greatly in quality, and sand that contains a large percentage of loam requires less time to bind it together; but loamy sand makes a very inferior plastering mortar. When lime of the best quality is obtained and good sharp sand is at hand, the proportions that enter into the mixture are uncertain and are guessed at by the laborer who does the mixing. This laborer is the unskilled workman of the job, and if he does not properly manufactnre the mortar all the skill in the world in applying it to the wall by skilled workmen will avail little.

This unsatisfactory state of affairs in making plastering mortar has now been overcome, as many manufacturing plants have been established throughout the country which slake lime by machinery, dry the sand, card the hair, automatically weigh the proper proportions of each and mix the whole together thoroughly by machinery and deliver this mixture in a dry state to the building in suitable containers, usually jute bags. As the material so prepared requires only water to be added at the building to make it ready for use it does away with a great many of the disadvantages of the old way, and has the great advantage of insuring a uniform plastering mortar of very superior quality that is easily handled.

Plastering mortars prepared in this way can be taken into the building and mixed with water in water-tight boxes on the floor where it is to be used, and this avoids all chance of freezing if the building is properly heated, as it should be.

In the treatment of some of the troubles encountered in plastering in winter, we will not consider those met with when plastering mortar is made at the building in the open in the old way, but will consider that if the mortar is made at the building that it is properly protected as far as its manufacture is concerned. With this exception the following comments apply equally to all kinds of plastering mortar.

Plaster is necessarily applied in a wet state and the surplus water has to evaporate or be dried out of it. It is this surplus water and other dampness in a new building that are the chief causes of trouble in winter plastering.

The amount of dampness in a building is very much greater than is usually supposed. In frame structures there is moisture in pretty much everything that enters into it, the brick in the chimneys, the cement concrete in the cellar and bath rooms, even the lumber contains much moisture. In the larger brick or stone buildings with thick walls, concrete or tile floors the amount of moisture is very great. The greater part of this moisture will have to be dried out of the building sooner or later, but until this is done it is liable to be a source of trouble, and this is particularly the case in winter.

The methods used to get rid of this moisture are for the most part crude, and in many cases are the causes of greater trouble than the moisture itself. In hardening, the plaster of paris and lime in wallplaster combine chemically with some of the water, either in the form of water of cystalization or in formation of hydrates. Therefore, all of the water added to wet the plaster does not have to dry out. The so-called hard or patent plasters all contain more or less plaster of paris, they do not require as much water to be dried out as other plasters that do not contain plaster of paris; in other words they dry quicker. This chemical change or hydration takes place gradually, and it is not desirable to dry the plaster so quickly as to prevent its taking place properly. An overheated building is quite if not more injurious than an underheated one. The majority of builders regard the ideal drying conditions in winter an overheated tightly closed building withnn circulation. This is far from being right. Circulation of air is, if anything, more important than heat, if the outside atmosphere is above freezing. On such days as the atmosphere outside is very damp and moist, it is better not to open the windows.

The ideal condition is to have a gentle heat to keep the atmosphere warm, and allow sufficient circulation of air to absorb and carry off the moisture. It is especially important that the heat should be kept up during the night. The proper way to accomplish this is to have the heating apparatus installed in a building and in working order before any plaster is applied. Temporary connections can be made and heaters placed in the middle of the room. By doing this and observing the simple precaution of opening the windows from the top during the day time to allow a free circulation of air to let the moisture out, the greater part of the troubles of winter plastering would disappear. No time is gained by not doing this, and it is a mistake to think that a building can be plastered quicker by starting the work before the building is properly heated. On the contrary it is much quicker to delay starting the plastering until the heating apparatus is in working order, as the plaster dries out within a few days' time in this case, whereas it is liable to be weeks and months when this is not done.

With a temperature sufficiently high to evaporate the moisture, the plaster dries quickly, and the rest of the work can follow at once, but the usual method is not to wait until the heating apparatus is in order, but to enclose the building with muslin screens and use stoves, salamanders or open fires to dry out the building. Usually the fires are not kept going at night, and in consequence the building (which has probably been overheated in the day time, as is always the case of the ceilings in the rooms in which the stoves or salamanders are placed), is allowed to become cold at night. The chances are, too, that no precaution has been taken during the daytime to permit a draught of air to circulate through the rooms to carry off the moisture. What is the result? The heat of the day vaporizes the moisture and the cold of the night, after the fires are out, again condenses it and it settles on the plastered walls and is absorbed, or if the temperature is very low the moisture freezes on the face of the plaster, which is found covered with ice the next morning. In many cases this process of heating by day and cooling by night is kept up for weeks, with the moisture for the greater part still in the building at the end of that time, or possibly a sufficient amount of it has been gotten out to make the plaster appear sufficiently hard to finish, and the finish coat is applied. Each coat should be thoroughly dry before the next coat is applied.

After applying the finish coat of plaster all moisture from the under coats has to dry through the finish coat, and as the finish coat is denser and more compact than the under coats it takes very much longer for the latter to become dry after the finish coat has been applied than if this drying had taken place before the application of the last coat. The results are usually as follows:

1. The Effect of Dampness Remaining in Plaster.—The most serious effect of plaster remaining damp and soggy and not drying out in proper time is to cause it to lose its set or strength, and in consequence it does not become hard. In other words the result is the same as if the plaster has been retempered. It is a well known fact that with plasters or Portland cements when they are retempered their strength is lost.

As time goes by, therefore, the plaster that has been allowed to remain wet and soggy dries out, but it is very apt to fall from the wall or crumble away like so much sand.

2. Staining Due to Dampness.—The scratch and browning coats of plaster should be perfectly dry before the finish coat is applied. If the finish coat is applied before the scratch and browning coats are dry, any staining from the wood lath (sap) or from brick or terra cotta walls will be carried by the dampness through to the surface of the finish coat, leaving a discoloration or stain. All moisture in the scratch and browning coats, and for that matter in the brick walls as well, dries out through the finish coat, with the result that the latter remains damp until all this moisture has entirely dried out. This seriously injures the finish coat and it is liable to remain soft. In large office buildings where the walls are massive, the dampness remains in the plaster for a long time, and beads of water are frequently seen standing on its surface. In case of brick walls when the water evaporates it leaves long, fine crystals of substances that have been brought to the surface in solution. Usually these substances are crystals of carbonate of soda, chloride of soda or other soluble salts. The use of damp-proof paints on brick or terra cotta walls, before plaster is applied, prevents much dampness coming through the plaster and should be used whenever possible.

3. Effect of Frost on Scratch and Browning Coats of Plaster.—The general effect of frost on plaster is to seriously injure its binding qualities or strength. The plaster becomes soft and does not set hard, and the plastered wall that has been frozen, is liable to fall. If the frost has gotten into the first or scratch coat of plaster and causes it to lose its strength, it will not be strong enough to hold up the two succeeding coats (browning and finish), even though no frost has gotten into these last two coats; but should the scratch coat not be injured to such an extent as to cause it to fall, the frost will thaw out and in this process push off the browning and finish coats.

It is not an uncommon thing to see the browning coat separate from the scratch coat in large sheets where frost has affected the latter. In like manner, if frost gets into the second or browning coat, this will be damaged, as in the case of the scratch coat, and if the third or finish coat is applied while frost is still in the browning coat, the finish will be pushed off in sheets when the frost thaws out, just as was the case of frost in the scratch coat.

4. Effect of Frost on the Finish Coat of Plaster.—Frost causes the finish coat of plaster to become soft and chalky and without strength or hardness. The finishing coat rubs off like whitewash and is a constant source of annoyance to the occupants of the house.

5. Plaster Appears Dry.—Scratch and browning coats of plaster appear to be dry on the surface when, in reality, underneath the surface they are still wet. This appearance is often misleading and the finish coat is applied too soon, with the result of having the finish coat remain damp until all the moisture has dried out from the under coats. As the finish coat is less porous than the scratch or browning coats, it naturally takes longer for a wall to dry that has had the finish coat aplied while the under coats are still wet, than if the moisture in the under coats were allowed to dry out before applying the finish coat. This dampness in plaster is the cause of the disfigurement of decorations.

6. Staining and Cracking Due to Use of Salamanders and Coke Pots.—The sulphur and smoke from the coke or coal used in the salamander disfigure plaster. The smoke blackens the wall, but the sulphur of the coke unites with the lime in the finish of the plaster and forms sulphide of lime, which is yellow. These are the yellow spots or blotches that appear so often on the surface of plaster that has been applied in winter time. As the sulphur only units with lime when it is damp, these yellow stains appear in round spots, the moisture drying out in small circles, just as if water were dropped on blotting paper and were allowed to dry. These small damp spots absorb the sulphur of the coke and cause an unsightly wall. The small furnace used by the plumber also adds to this yellow staining. Coke pots, when placed to near the recently plastered wall, are apt to dry it too quickly, and, in consequence, draw the wood lath, causing the lath to twist or buckle and the plaster to crack.

7. Decorating on Plaster that is not Thoroughly Dry.—When plaster is damp, as shown above, the lime which is a constituent of the finish coat of all plasters (there is no exception to this rule) acts as a bleaching agent. Paper applied on damp plaster, therefore, will fade or discolor, and paint or kalsomine will be similarly affected. Naturally the more delicate the tints of paper or kalsomine the more liable they are to be affected. Often rooms are repapered and repainted, and even the second application of paper or paint is spoiled. If the dampness in the wall is excessive, the paint is pushed off from the plaster and peels off in spots several inches in diameter.

Walls should be thoroughly dried before they are decorated and this takes time. If proper care has been taken in heating the building when the plaster was being applied, and this heat has been kept up until the trim is on and the walls are hard and dry, there is no reason why with proper precaution the walls cannot be decorated. Paint is very much less affected than kalsomine or paper. Delicate shades of either are more liable to damage, but if the walls are properly sized they can be decorated with satisfactory results. If very expensive decorations are to be made directly on the surface of the plastered walls it is best to allow the walls to become seasoned for at least one year. When decorations are on canvas or if burlap is used instead of wall paper little trouble is experienced. The trouble lies in the mistake that plaster that is hard and does not feel wet to the touch is considered by most persons to be dry, but this is far from the truth.

As poor drying conditions in winter are the cause of the troubles of plastering in winter, replace them with proper drying conditions and there will be no trouble. This can be easily brought about by observing the following simple precautions:

First, a building should be well enclosed. Nothing is gained in time by starting plastering before a building is properly ready to be plastered.

Second, a building should be well heated by furnace, steam or hot water heat. Salamanders, coke pots, stoves or open fires should not be used. They are not necessary and their use does not hasten the work. If, however, they are used their bad effects can be materially lessened if care be taken in their use. In case of coke pots or salamanders have them lighted out of doors, so that the first smoke will pass away and the coke become well ignited before they are placed in the house. Coke should always be used and not coal, as there is less sulphur in coke and less smoke than in coal.

Third, a building should be well ventilated. The windows should be opened from the top in the daytime and closed at night. This allows the current of air to circulate through the building and carry out the dampness. It is a great mistake to keep the building tightly closed during the time it is being plastered. Fresh air is a good dryer.

Fourth, if the precautions in regard to properly enclosing, heating and ventilating a building are looked after carefully, there will be little trouble with winter plastering. It is not well to paper or paint too soon on new plastering. Even under the best conditions, the plaster finish acts as a bleaching agent, and it should be well seasoned before it is decorated. When it is necessary to decorate quickly, the precaution should be taken of using canvas or an extra heavy coat of sizing before either papering or painting.—D. L. Haigh in Engineering Record.

—THE—

CANADIAN ARCHITECT AND BUILDER

Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited

Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

38 ALLIANCE BUILDING, MONTREAL.
Bell Telephone 2299.
720-721 UNION BANK BUILDING, WINNIPEG.
21 GREAT ST. HELENS, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements will be sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities,

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

BOARD OF DIRECTORS:

W. D. McKILLICAN	Chairman
E. W. WHITTINGTON	Secretary
THOS. CATTERALL	Treasurer

Mr. Sanford F. Smith, of the firm of Sanford & Smith, architects, Toronto, was married on September 28th to Miss Mabel Beatrice Breyman, of Ottawa.

At Woolwich Arsenal recently transverse breaking tests were made of plate glass from several factories. The thickness of the glass varied from ⅛ in. to 1 in. and the span from 8 ins. to 24 ins. The modulus of rupture, which ranged from 2000 lbs. to 8,000 lbs. per sq. in., was generally greater with the lesser thicknesses. Of the various kinds of glass tested—rough, ribbed, polished and wired—there was little difference in strength except that the wired glass showed a little greater strength than the other kinds. The strength was also greater for the "sandwiched rolled" than for the solid rolled wire glass. The strength of glass set in frames was practically double that of the specimens tested transversely.

The Duty on Architectural Plans.

The Ontario Association of Architects are endeavoring to have changed the present customs regulation fixing the amount of duty to be paid on plans brought in from other countries. Until a few years ago, duty was charged not, as at present, on the value of the plans only, but on the total value of the completed building erected from the plans. In some way the regulation was changed so that duty has to be paid on the value of the plans only. The regulation in its present form is felt to be unfair to Canadian architects, and an effort will be made to induce the Government to revert to the former regulation.

Power From Refuse.

Perfection in municipal arrangements is to be found in Great Britain rather than on this side of the Atlantic. They have crowded cities over there that must be well run if they are to be run at all to suit the English taste for having things in good order. It would do us good to cultivate the same taste and, even at some little cost, to qualify the prevailing shabbiness of our towns. But it is not cost so much as economy that would result from a study of English municipal methods. Administration is the forte of the English and they are making their municipal works pay in many ways. In the matter of refuse destructors, there are said to be one hundred now in operation which supply power for electrical purposes, sewage pumping or water pumping, equivalent to the use annually of 150,000 tons of the best steam coal. An average annual saving of 1500 tons of coal wherever one of these destructors is used must offset the working cost considerably, but there is another point worth considering—that combined works of this kind are better worth having than works where the power is not utilized, inasmuch as the high temperatures which are essential for satisfactory power production are at the same time a guarantee against nuisance.

Concrete Piles

For wet and dry conditions in a piled foundation concrete piles have recently been used successfully as reported in the Engineering Record, in building the Dittman factory, on the canal in Cincinnati, Ohio. The piles ranged from 8 to 22 ft. in length. They were square in cross-section, with a 2 in. bevel on the edges, and tapered 2 inches in 16 feet; being 10 in. square at the point end and 14 in. at the upper end of a 16 ft. length. The piles were reinforced with ¾ in. twisted bars, one in each corner, and these were bound together with ¼ in. hoops, 12 in. apart on centres. These bars turned in at the bottom into a cast iron shoe weighing 50⅔ lb. As it was desired to drive them as soon as possible after being made, a 1 : 2 : 4 mix was used. The piles were aged at least four weeks before being driven. In order to keep the top of the pile from fracture a special cap was used, which was stuffed with rubber from old hose. The hammer used was two tons, and the drop averaged from 4 to 6 ft. Higher drops were used but the record was against them. The cost of the piles is only stated as "considerably more than the cost o

wooden piles per lineal foot," but it is added that "one concrete pile was as effective as two or more wooden piles would have been.

Bad Scaffolding

Mr. R. J. Fleming, Commissioner of Assessment and Property in Toronto, has given his opinion that scaffolding cannot be efficiently inspected by city officials. It would require an army of them, he says. As scaffolds are often put up only for a few hours, it would be quite possible for a scaffold to be erected, to break down, and the workmen who tried to use it to be dead, within an hour ; while the department was still in ignorance of it being erected. The matter, Mr. Fleming thinks, should be dealt with by the workmen. If, he says in effect, through their organizations, they can decide how many hours they shall work, how much they shall be paid for their work in those hours and beyond them, how many hod carriers a bricklayer can keep going, how many lads ought to learn the trade—if they can do all this, surely they can decide the character of any scaffolding upon which they have to work. He might have added that, if work is to get on without continual delays, there must be some more concurrent way of assuring the safety of a scaffolding than by depending upon a visit from a City Hall official.

Clay vs. Iron Drain Pipes.

Modern building by-laws in Canadian citres require that nothing but iron pipe shall be used for drains within the walls of buildings. Outside the walls vitrified clay may be and is frequently employed. In England, however, there appears to still exist a diversity of opinion regarding the relative merits of the two materials. Mr. Samuel Smith in a paper presented at the recent Glasgow Congress of the Sanitary Institute argued strongly in favor of the use of vitrified clay-pipe as against iron-pipe for this purpose. He advanced the opinion that clay-pipe would withstand the action of acids which would cause corrosion in iron pipes.

As a proof of the ability of clay-pipe to withstand hydraulic pressure, he pointed to tests made to determine this question, showing that a 4 inch diameter fireclay pipe was tested up to a pressure of 45 lbs. per square inch without showing signs of porosity. Another test was made to find the exact pressure that a pipe would stand and still be air-tight. The pressure was gradually increased at intervals of ten minutes from .5 lbs. till a pressure of 3.3 lbs. was reached, and the mercury in the manometer remained steady at that pressure for twenty-four hours. From this test it was concluded that the pipe was capable of standing a pressure of 3 lbs. per square inch, or twenty times the pressure required to break a three-inch seal of a washdown closet. Fire-clay pipes were also submitted to a hydraulic pressure of 250 lbs. per square inch without showing signs of fracture, but under this pressure there were signs of porosity in one pipe at 60 lbs. pressure and in another at 100 lbs.

Mr. Smith admits that clay pipes are liable to fracture if not carefully and evenly bedded, and also that great care is required to insure tight joints. To overcome the former difficulty he recommends the laying of a bed or layer of concrete underneath the pipes, and if the ground is very soft or unequal, the use of ferro-concrete. For joints he recommends that nothing be used but slow setting cement thoroughly cooled and and aerated and well staved into the joints so that all the air from the cement is forced out. To prevent breaking of pipes by reason of the settlement of the building, it is recommended that the openings be ample in size and linteled over with a space between the lintel and the pipe.

Mr. Smith's paper has been severely criticized by Mr. W. R. Purchase, building inspector of a Borough Council, who was formerly Superintendent of a large pottery where drain pipes were chiefly made. Mr. Purchase regards the advocacy of clay pipes as a retrograde step, and contends that porcelain iron pipes are the best material to be obtained at the present time for drains, their points of superiority being strength and capability of resisting fracture, reduction in the number of joints (6 ft. and 9 ft. lengths compared with 2 ft. and 3 ft. lengths of clay-pipe) and the greater security of the joints, which are run in molten lead. The weak points in clay pipes he declares to be porosity and weakness in the material, expansion and contraction of the cement in the joints, uneven expansion of concrete, careless filling in of trench by ramming, etc. In this writer's opinion, the drain of the future will be laid in a brick or concrete culvert with stone cover and chambers for access (sufficiently large to admit a man) for the purpose of periodical inspection, the drain to be laid on blocks about 9 inches above the floor of culvert and at intervals of about 3 feet apart. These culverts might also be used for laying the water, gas and electrical mains.

Architects for City Improvements.

The address of Mr. E. Guy Dawber to the Architectural Association of London, from which extracts are quoted in another column, treats at some length, in an address to students of architecture, upon street character as a matter for consideration by architects when building, and implies that street planning should come within the scope of their studies. Mr. Aston Webb, in commenting upon the address, goes a step further and gives it as his opinion that architects should be consulted about "the formation of new streets." As a matter of fact the rearrangement of the approach to Buckingham Palace, made in connection with Mr. Aston Webb's Memorial to Queen Victoria in front of the Palace, is so well done that, though it replaces the old rurality of the Mall, cherished and regretted by Londoners, there is no one who does not accept the improvement with satisfaction. The simplicity and serviceableness of the changes are remarkable ; the place looks as if it had grown that way ; yet the total result is a dignity which makes the Mall, what it was not before, a proper approach to a palace. Anyone who can appreciate the refinement of desigu which has gone to make this result will understand also that it is in the line of an architect's training rather than an engineer's. Mr. Daniel Burnham's usefulness in this direction is recognized by the United States Government. Mr. Burnham is now engaged upon the project of transforming Manila into a modern capital at the cost of many million dollars. He is said to have declared his intention of following the plan which was originally proposed for Washington but was not carried out.

SOME NOTES ON THE QUESTION OF FIREPROOF CONSTRUCTION.

Among the crop of utterances upon the subject of the Baltimore fire we have one now about thicker walls and better laying. These are very simple remedies and, if Capt. Sewell, U.S.A., is right, in his inference from the appearance of fourteen inch walls, that an eighteen inch wall would have stood the heat, the demonstration is one more in the direction of proving, what is much to be desired, the unity of Science and Art. Science is truth and Art is truth, and, where they do not agree, the thing to expect is not their divorcement but a fallacy in one or the other. Mr. Wells, the writer of scientific fiction, groans over the backwardness of the age ; still making walls by the slow process of setting units one upon another ; still wasting time and material in a process that requires walls to be a foot thick to enable them to keep up. Why, he asks, go on with this, instead of setting up a steel cage in a four inch form and pouring in cement ? These anticipations make an architect shiver. Not that he would keep back science. It is the suddenness of the change, that is all. But Mr. Wells has to be sudden or he won't sell ; and Christmas book science is not as safe to lean on as that of West Point and the U.S.A. We can hardly expect any substance to resist the inroad of great heat except by sheer thickness. Capt. Sewell declares that more mass is required to resist a fire than to carry superimposed loads. So we may enjoy the satisfactory reflection that after all the eye is the best measurer of thickness ; that a wall (special circumstances apart) is usually strong enough when it looks strong enough ; for though science, in its most economical precision, would be content with less thickness, capacity for resisting fire requires it all.

In the mean time the new building law for Cleveland, having specified the acceptable fireproofing materials in order of merit as follows :—Brick, porous terra cotta, semi-porous terra cotta, dense terra cotta, concrete, and plastering on metal lath, proceeds to declare that the least thickness of fireproofing material that will be allowed is 2 inches. That is to say, 2 inches of plastering on metal lath is sufficient protection in a fire where a 14 inch wall will not stand. These two statements do not seem to make a very good pair.

The extraordinary thing is that there should be really any doubt about the action of fire when we have had so much experience and when it all counts—for fire never changes. What happened in one big fire will happen in the next, as far as the fire itself is concerned; and, if we are too busy during a fire to study its action, and are not able to read the records it has left behind it, there is nothing to prevent our having a laboratory conflagration and watching its progress through glass. Indeed this is done in effect by The British Fire Prevention Committee, and occasionally for the purpose of special experiment, by other bodies, on this side of the Atlantic as well as in Europe. It will be part of the work of this journal to keep track of such experiments and give practical results to its readers ; but it is high time that such results were not only practical but practicable, and found their way into specifications instead of into files for future reference.

It is time to change our ways. The statement has been made, in a paper read before an English insurance society, that the recent losses to English companies by conflagrations in this country have exactly wiped out the profit to their shareholders during the last fifty years—and the vipers are going to rise the rate on us. This seems to mark a crisis. It is a hint that we are not quite within the pale of civilization. It appears that the people of the United States are in it too, but that should be no encouragement, for they are quick movers over there, and before we know it we shall be alone, marked down for burning, by people with whom probabilities are a science a trifle too exact to make it a comfortable matter to be on the list of suspects.. It is time to change our ways. The question is how to change them effectively. There is no use in talking fireproof construction ; we have done that. There is no use in blaming the architects ; they know all that is known about fireproof construction and would be glad to practice it. It is the architects' clients who condition the state of building and they are the people we have to deal with. The truth about the halting progress of fireproof construction in this country is that the business public do not want fireproof buildings. They would like their buildings to be fireproof well enough, especially after a big fire ; but the wish dies a painful though not a very lingering death under the influence of preliminary estimates for rebuilding with fireproof construction. A conflagration is but a chance after all and the cost of fireproofing is a certainty, and it is not business to balance a certainty of cost against a problematical advantage. There is some return in the reduced cost of carrying insurance but it is not enough to even up the transaction, and there is practically "nothing doing" in fireproof building.

Then comes the cry for stiffer by-laws. Let us force them to build fire-proof ; the extra cost is not a matter of choice, it is a public matter. Very well, let the public establish preferential trade with the owners of fireproof building in proportion as their buildings are fireproof and their prices therefore high. This is a perfectly fair proposition, but in view of the fluidity of cash, which flows steadily to the lowest levels, it amounts to a proposition to make water run up hill. How then is the suggestion to be carried out? It is still true that if the public have a right to say they have a right to pay. How can the public, who share in the advantage of an individual's fire-proof building, share in its extra cost? It is at any rate not to be brought about by sending the Assessment Commissioner after him to rate him for extra taxes for the public benefit on the score of his extra expenditure in building so as to benefit the public. This would not be a good thing to do, but it seems to suggest what would. If a man taxes himself for the benefit of the public it would not be fair (to him) to tax him again on the amount of his own taxation, but it would be quite fair (to other people) to remit taxes to him on the basis of that amount ; and, inasmuch as taxes should be fluid also and level up all hollows in the public estate, the displaced tax should find its settlement on buildings that are below proof in the matter of fireproofing. It is for them and because of them that the firehalls are maintained, and they should pay for their maintenance. Here then is, if not a complete proposition, a suggestion of a direction in which to feel for a string which will make fireproof construction sit up. It would be interesting to figure out the relation between the extra

cost of a fireproof great-risk district and the cost of the fire halls which supply it, to see how far one can be set against the other. There is a proportion of the cost of water supply also which might fairly be charged against the people who won't provide against fire and removed from those who will. If the financial arithmetic works out the working machinery could be devised and then we should have fireproof building settled upon a commercial instead of upon a speculative basis: quod est desiderandum.

STUDENTS' COMPETITION.

Architectural students are invited to send in on or before February 1, 1905, a sketch for a house in a country town, suitable for the residence of a person whose income is $1,500 a year. The house is to be placed on a lot 70 feet wide on the street front by 110 feet deep. The lot is situate on the south side of a street. A block plan must be furnished showing the position of the house on the lot and the arrangement of the grounds. The owner may be supposed to keep no horses or other animals but to be fond of gardening. The plan of the ground floor is to be shown in full on the block plan. Other drawings required will be: 1, the plan of the first floor; 2, the rear (or south) elevation; 3, a perspective showing the front and one side; 4, an elevation of the other side. All drawings to be to a scale of 16 feet to an inch. They are to be drawn in line with India ink on smooth paper or cardboard and are to be arranged within a space in the proportion of 8 inches by 12, and, if possible, no larger than that size. The scale of the drawings is to be, not merely noted, but drawn on the paper. A brief description of the material used in the construction of the exterior must accompany the sheet of drawing. Both drawing and description to be marked by a cipher or nomme de plume, and the author's name, enclosed in a sealed envelope similarly marked, must be sent under cover addressed to the C. H. Mortimer Publishing Company, Confederation Life Building, Toronto. Judgment of the sketches will be made by a committee composed of members of the Ontario Association of Architects and of the Eighteen Club of Toronto. The following prizes are offered: First, $15.00; second, $5.00; third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER, Architects' Edition.

PICTURES WITHOUT LENSES.

Pinhole photographs are obtained by means of a pinhole punched in tinfoil and made to serve the place of a lens in the camera. Excellent pictures, strange and interesting, are thus obtained, and pinhole photography is becoming one of the fads of the day. The pictures lack the extreme sharpness of those obtained by a regular photographic lens, but they have a greater softness of tone which is delighting to the eye and which is equalled only by the artist's brush. A needle serves better than a pin for punching the hole in the tinfoil. The hole must be perfectly round and smooth. Through this the light is admitted to the sensitive plate, the exposure being made in the regular manner. Mr. N. R. Briggs, who has made a study of the new-style photography says:

"The interest manifested in this new objective is due to the fact that it is of universal focus, the rays focusing in the stop; the perspective is true, no part of the picture being out of focus, while interior and architectural photographs are rectilinear, that is, without distortion of any kind, for the rays of light fall directly upon the plate without any interference. It is said that work requiring the sharpest definition, such as copies, reproductions documents, etc., can often be done better by the pinhole objective than with a fine lens. The reason is obvious. A lens often focuses sharper than the eye, giving a staring, unnatural effect to the resulting print."

The Scientific American says: "Another singular feature in connection with pinhole photography is that any size camera may be used. For instance, it will take a picture upon a plate three inches long or twenty inches long. Therefore, it will be seen that all one has to do is to arrange this camera for a small or large plate; and with the latter, interesting panoramic views could be secured. There is no doubt that a very cheap and satisfactory folding camera, in which to use any of the present series of roll films, could be made for special panoramic work."—The TechnicalWorld.

COST OF VENTILATION.

The cost of ventilation in several notable buildings in Great Britain was referred to in a recent paper by Mr. William Henman before the Royal Institnte of British Architects on the plenum system of ventilation. The Glasgow Art Galleries supplied with 9,050,000 cubic feet of air per hour by electric power requiring 66 horse power, costs for power about $1,450 per year per 1,000,000, cubic feet. The Manchester Technical School, supplied with 12,000,000, cubic feet per hour, providing for 3½ changes hourly and requiring 80 horse power, is charged with $1,308 per year per 1,000,000 cubic feet. The Manchester Midland Hotel, ventilated at the rate of 3 changes of air per hour, corresponding to a supply of 6,000,000 cubic feet in that time is charged with 40 horse power electrical energy at an annual cost per 1,000,000 cubic feet of $1,308. The Birmingham General Hospital, with 7 changes per hour or 13,000,000 cubic feet supplied per hour, requires 19 horse power electrical energy and costs about $287 per annum per 1,000,000 cubic feet. The Royal Victoria Hospital, at Belfast, designed by the author, provided with ventilation in turns of 7 changes corresponding to an hourly supply of 5,000,000 cubic feet, and is charged with but 5¼ horse power in a steam plant, costing $97 per 1,000,000 cubic feet per annum.—The Western Architect.

A very interesting piece of work in the way of house raising has recently been executed in Brooklyn, N. Y., in connection with public school No. 85. The structure is located in what is known as the "flooded district," the lower floor being covered with water at times to a depth of several feet whenever there are heavy rains. With a view to remedying this, the building, which is of brick and four stories in height, has just been raised nearly 3 feet. The estimated weight of the building is 7500 tons, and something like 1,000 jack screws were used in the operation of lifting it to its new level. The work was done by 75 men acting simultaneously, and after each turn of the screws the foundations of the building were thoroughly inspected in order to make sure that everything was progressing as it should. The work was done by Miller-Daybill & Co., and is regarded as more of an engineering feat than was the moving back several feet of the Brighton Beach Hotel some years ago, in order to save it from being undermined by the heavy ocean tide.

OUR ILLUSTRATIONS.

THE PALAZZO POMPEII-VERONA.

This fine palace is built on the bank of the river Adige and is a very characteristic example of the robust architecture of Sanmicheli. He was considered the greatest military architect of his day. His fortified gates still form the entrances to the city of Verona and his domestic work shares somewhat of their severe and powerful aspect.

Earlier endeavours to apply the Roman "orders" of architecture to buildings of more than one storey, going on the idea of superposing one order upon another, generally resulted in a strongly marked horizontal division with a lack of vertical connection and unity. The method of employing the orders in an entirely subordinate manner as mere framing to windows and doorways and then crowning the whole building with a huge cornice was satisfactory in point of design but did not satisfy the desire of the Renaissance architects to see the orders glorified to the utmost.

In this Palace Sanmicheli has made the classical order a feature of dominant interest, not simply placed upon another storey of varied design but provided with a basement which seems as essential a setting for such a colonnade as the upper stage itself seems a fitting crown for such a pedestal. The bold suppression of any projecting cornice between the two parts contributes largely to this excellent unity of effect.

This is one of the earliest buildings in which a classical order is placed upon a rusticated basement—a treatment again employed by Sanmicheli in the Canossa and Bevilacqua Palaces at Verona. It became one of the most favourite motifs in the later Renaissance of England.

CECIL S. BURGESS.

POST OFFICE, WINNIPEG.—MESSRS. DARLING, PEARSON & OVER, ARCHITECTS.

In plan this building has the usual post-office arrangement—space for the public along the front and side walls, working space in the centre, and the vestibule for the reception and despatching of mails in the rear, opening on a lane. The principal public space, where are the private letter boxes, is along the front—the ground floor of our illustration—and at one end, in the pavilion on the left, are the stair and elevators.

The dimensions of the facade are 134 ft. by 70 ft. to the soffit line of the cornice. The material will be Tyndall stone throughout. The building is of skeleton steel construction, with floors of terra cotta arching covered with four inches of cement and a hardwood flooring. The stairs are of cast iron. The flooring and the doors are the only structural wood. The window frames are of metal and are glazed with wired plate glass. The windows have also iron shutters. To deal with fire within the building, five stand pipes are arranged.

Provision has been made in the basement for establishing the plant necessary for a pneumatic tube system.

Examination of the design shows a simple arrangement of five bays and two pavilions, kept broad by due distinction between the bays and the central portion of the facade, and by subordination of the horizontal lines of all windows between the basement and the cornice, and harmonized by a balance between the scale of the three storey order and the rustication of its setting. The rustication of the basement is carried up into the pavilion and these are further distinguished by the vigorous subtlety of the pedimented composition which unites the three storeys of windows. The cornice bounds the whole, and the composition up to the attic is a fine piece of rich harmony. The attic, which will, no doubt, in execution have to dispense with the support of the roof from ordinary points of view, has been given an interesting skyline by combining dormers with the balustrade. The top storey of the pavilion, being above the cornice, makes a complication difficult to treat. It partakes partly of the nature of an attic, which must be kept down, and partly of the nature of a crowning member, which should be enriched.

It is worth noting that the architects have helped their own building by accepting as far as possible the vertical heights of the existing adjacent building. Their own composition gains by treating the other as an appendage and they have certainly saved the life of the little one, and—which is a great point—helped instead of injuring the street.

THE MODERN AMERICAN HOUSE IN THE ARCHITECTURAL RECORD.

The October number of the Architectural Record is devoted to a study of the Modern American House. In a preliminary chapter the writer deplores the present state of affairs in which the decorator is independent of the architect. "One man or one firm," the Record says, "should do all the necessary designing, and the function of the professional decorator should be to carry out the architect's ideas. . . . The architect, whatever his limitations, alone represents a good aesthetic tradition. The American business man and his wife have no aesthetic traditions at all. . . The professional decorator may have in his employ designers as competent as the average architect, but"—he is in short in business and his only concern with his client's state of taste is to satisfy it and take his money. "He works entirely by routine." The writer might have added that the decorator's competent designers must be very competent indeed if—especially in the time usually at their disposal—they can fall in exactly with the taste of every architect. It needs moreover a liberality of mind such as we do not find, for instance, in the distinguished foreign artist in Punch who, replying to the owner's objection that a proposed scheme of decoration will kill his high blue dado, says, "'E is a beast, your 'igh blue dado, and I veesh to keel 'im very mosh indeed."

The writer has no sympathy with the æsthetically austere and ungracious rooms which some architects seek to force on their clients. The demand for a cheerful, comfortable and homely atmosphere in a dwelling is absolutely a legitimate demand, just as the demand that the interior should be thoroughly designed is also legitimate; it is the action and reaction between these two demands which will most effectually serve to give American (and Canadian) interiors the mixture of propriety and distinction which they need. At present distinction is too often obtained at the expense of propriety and comfort, and propriety and comfort too often obtained at the expense of distinction.

In the matter of the Hall, the Record seems to be quite complacent about the treatment of the hall as a sitting room "even if by so doing the other rooms of the house on either storey are somewhat crowded or diminished in number." This surely is distinction at

the expense of propriety and comfort. The house in which the necessary accommodation has to be "somewhat crowded" in order to admit a hall large enough to be planned as a sitting room is in the category of people who aim at the distinguishing marks of those who are in a superior class. To give a small house the style of a large one and a city house the freedom of a country house is at the bottom of the feeling that prompts to made of the hall "a sitting room differing from others by the fact that it has no solid partition between it and the entrance hall." Cold comfort, one would say, and scant seclusion! The separation of the staircase from the hall is another thing and there are some suggestive illustrations of halls in which the course of the stairs is concealed or partly concealed, sheltering the stairway from draughts and the persons ascending and descending it from observation. The writer in the Record thinks "these are always dangerous to the designer, because the raking lines of the stair are always difficult to manage and produce ungainly spaces, shapes and combinations." The application of this statement is evidently to the partly screened staircase, but the illustration, which shows a good deal of the stairs, does not suggest any danger to the design from their raking lines appearing, and certainly not one one would think from their appearing less than usual. Much concealment meets the writer's approval; "the more a stair can be built in between walls generally the better thing it is."

The living room brings out no special doctrine except the general assumption of such a room, (when it is not crowded out by a hall sitting room), and its qualification by a smaller room opening off it, which qualification may take either of two directions: The small room may be a more intimate room into which to retire for greater privacy, the large room being practically a drawing room; or the small room may be a less intimate room, intended to hold strangers off so that the large room may be devoted to the family and their more intimate friends.

The illustrations of the living room are however well worth studying; but one should have a pretty strong reading glass with which to examine them, if one is not to be daunted by their apparent size. In order to receive a true impression from a photograph of a room it is necessary to get the size as nearly as possible in the position of the camera when the photograph was taken; that is to say as nearly as possible against the surface of the paper. Otherwise the room appears much larger than it is; being measured in an illusory manner by an instinctive extension of the perspective lines to a vertical plane at the position of the eye. A good reading glass, giving nearly the true point of sight, enables one to realize the design in small photographic illustrations, and when the half toning process work is not too coarse, adds greatly to the pleasure of looking at them.

The section devoted to the dining room makes one in love with the circular dining table. There is in the the first place, if not a saving of space, a better application of it. A table 5 feet in diameter is said to seat eight persons comfortably. That means a little less than two feet for each person at the table's edge. This would not do at a rectangular table, but when one reflects that the governing condition for seating space at a dining table is not plate-room but elbow-room, it is clear that the trapezoidal space occupied by a sitter at a round table favours this, for the space increases with distance from the table and elbows do not (in the first families) come to the front. Moreover an important factor in chair spacing is room for service, and this is automatically taken care of, when the table is round, by the greater separation of chairs at the back.

So the round table has points in its favour beyond the square, which is also advocated in the Record; but, as far as the room is concerned the conditions are the same; "the long room will be found much modified." The oblong room is a fine thing and we may miss it, but not in a small house. There it is a crux, and a room that is square or approaching the square will fall in much better with the rest of the house. The room need not however be square; there is other furniture, besides the table, to be provided for. The table may be placed at one end, and the attractive proposition is made (for houses in which summer is the chief consideration) to treat this end as a projecting bay which, if its windows are made to open up well, will be "almost the equivalent of a verandah."

Among the illustrations of dining rooms is one in which there is a high wainscot, finishing in line with the top of the door architraves and leaving just enough space between its shelf and the ceiling to place some oil portraits, all of the same square size. This would be fine if it were not that the portraits (no doubt in order to be seen) lean forward a little, and so come in front of the wall beam of a heavily moulded plaster celling. This is a pity but affords a suggestion that in rooms of moderate extent, which are finished in this way with pictures or decoration on the wall surface which remains above a high dado, that portion of the wall should lean slightly, as the portraits do in this illustration.

In the bed room section the principal point is advocacy of its arrangement so as to serve also as a sitting room, by partitioning off the toilet apparatus and (of bedroom furniture) leaving in view only the bed. The suggestion is made that we should take a hint from the hotels and place the toilet closet and the hanging closet on the inner end, leaving a vestibule to the bedroom between them. Most Canadians will require to be sunk a little deeper in civilization to come to this proposition cheerfully. The closet (with electric light or even with a window on the room side) is all right, but the proposal to light—and ventilate—the toilet room from the hall makes one's heart sink. With a rotunda down stairs in the hall and borrowed lights in the bedroom passages there would be too much hotel about the house. The writer, by the way, speaks of a fanlight over the bedroom door as if it were a recognized necessity; it is a question whether it is not more generally recognized as a nuisance. In the very plan in The Record, which is supposed to have a fanlight, the proper means of bedroom ventilation is shown, in the shape of a bay window; and unused, as one side is unlighted though there is no apparent objection to its having a window. We are too apt to stop our bay windows with the living rooms; whereas in the bed rooms, where they furnish the necessary choice of direction, to avoid much exposure in a window that will remain open while we are asleep, (or in summer to get it,) the bay window is a boon. A circular window of the kind forms an essential part of the plan which is presented to us in The Record as perfect—and perfect it is. Here the toilet compartment has a window of its own and a door of its own: it is in fact a dressing room. The proposition therefore becomes that, if we wish to make a sitting-room of a bedroom, we must have a dressing room attached to it. The situation implied by these precautions about toilet furniture—the reception of visitors in a bedroom—is not after all a common situation. Where it occurs, the Universities offer another hint, perhaps better. A slight extension of the dressing room makes room for a single bed. The bed room and sitting room are thus made quite distinct by day while at night they become one good sized sleeping room.

The kitchen description is on a scale of such splendour—glazed tile walls, rubber tile floor and "a telephone to each bedroom, hall, drawing room and dining room"—that it almost quells practical interest. With the exception of the telephone—suggestive of a practice of eating between meals, which is to be deplored—the rooms and fittings are however only a high expression of conditions that are necessary in all kitchens, and the section, which is chiefly concerned with the usual appliances, is well worth reading.

COST PLUS A FIXED SUM CONTRACTS.

The following circular letter from Frank B. Gilbrett, general contractor, New York, has been furnished by a prominent contractor in reply to a letter from the office of the CANADIAN ARCHITECT AND BUILDER asking for an explanation of this system.

DEAR SIRS,—I would like to explain to you in detail our method of contracting for building construction on a basis of Cost-Plus-a-Fixed-Sum. In 1901 approximately 30 per cent. of our work was on this basis; in 1902 45 per cent.; and during the year 1903 we completed contracts amounting to several millions of dollars, 70 per cent. of which was on the above mentioned basis.

When about to contract for work on this basis, we proceed as follows:—When the general plans are ready we estimate by the cubic foot basis what the actual cash cost of the proposed construction would be to us. We figure 10 per cent. of this estimated cost, and call it the fixed sum referred to above. For example, if we estimate that a certain piece of construction will cost us $150,000, we contract with the owner or his representative to do the work for actual cash cost to us plus $15,000.

By contracting for work on this basis the following results are obtained:—

First—The owner gets the building at a minimum cost.

Second—The building is completed as rapidly as is consistent with good workmanship.

Third—The owner is insured the best workmanship.

Fourth—The construction goes on without disputes over extra work and costs of changes. The owner can have the architects change the drawings and specifications at any time, knowing that there will be no dispute or delay in the construction made necessary by adjusting compensation to contractor.

Fifth—The owner, or his authorized representative, has at all times full control of the construction.

If we consider each of these results more fully, I may be able to explain how they are obtained.

1. "The owner gets the building at a minimum cost." From an owner's standpoint the cost of the building may be divided into three parts, the cost of (a) labor; (b) material; (c) contractor's profit.

The labor (a) on such contracts is handled as follows: we put on to the contract as many men, and these of such trades, as we believe the conditions require. We aim to have the best possible labor, but if the owner or his representative is not satisfied he may substitute other labor or discharge any man, at any time, without giving a reason for so doing. This insures getting the best possible labor.

The materials (b) are obtained in the following manner: we carefully schedule each and every class of material required, and attach to the schedule shop drawings, when such are necessary, so that every concern estimating on materials knows exactly what is wanted. For example, the cut stone schedule has attached to it shop drawings showing every stone in such detail that the stone cutter can cut all the stone from these schedule drawings. These schedules are submitted to all concerns that we know to be reliable and equipped to furnish the materials. We are particularly well qualified to get estimates for furnishing materials; not only because we have clerks in our employ whose constant work is that of making schedules and obtaining subbids, but also because we have offices in New York, Boston and Baltimore. The owner or his representative is also furnished with copies of these schedules, so that he can himself call for bids for furnishing the required materials if he so desires. The sub-estimates, being based on the same schedules, are very easily compared; and, after considering price, time of delivery and capacity of the sub-contractors, we send them, with our recommendations, to the owner or his representative, in concise form on a blank called a quotation list, which is especially designed for this purpose. We then award the contracts in accordance with the instructions of the owner. Orders for materials are in triplicate; one copy goes on record at our office, one copy goes to the owner's representative immediately, and the third copy remains in the order book. By this method the owner, his representative and the contractor are able to tell at any time what the itemized cost of the construction has been to date.

From the above it is obvious that the owner or his authorized representative has full knowledge of the cost of materials even before they are purchased; and I think it is also clear that the materials are obtained at a minimum cost.

Concerning the contractor's profit, it may be said that the contractor receives only a reasonable compensation for his services. This being fixed before he starts the construction, remains unchanged. The owner should certainly expect to pay said compensation on all construction, especially when he considers that the fixed sum is not all profit to the contractor, who furnishes plant, etc., gratis. On percentage work there is sometimes a feeling that the contractor is running up the cost to increase his profit. This does not occur when work is contracted for on a basis of cost-plus-a-fixed-sum. When the profit is a fixed sum there is no incentive to the contractor to increase the cost. When work is contracted for on a lump sum basis, there is an incentive to slight the quality of the work, and to let the work drag along slowly.

This proves, I think that the contractor's profit is best dealt with by the cost-plus-a-fixed-sum method of contracting.

2. "The building is completed as rapidly as is consistent with good workmanship." Since the contractor gets no compensation for length of time, he will naturally complete the building as rapidly as possible, so as to obtain his compensation, and to have the use of his plant elsewhere at as early a date as possible. When work is being done on a percentage basis it is generally slow and costly. This is not the case when work is contracted for at cost-plus-a-fixed-sum.

3. "The owner is insured the best workmanship." This is obvious, for the reason that it will in no way be to the contractor's advantage to do any but first-class work. If he did poor work he would lose chances of getting other contracts from the same parties. This we realize to be very important, since seventy per cent. of our work last season was from owners and architects for whom we had previously completed contracts.

4. "The construction goes on without disputes over extra work and costs of changes. The owner can have the architects change the drawings and specifications at any time, knowing that there will be no dispute or delay in the construction made necessary by adjusting compensation to contractor." As charges for extra work do not affect the contractor's profit, there is no cause for dispute. The construction goes on as smoothly as if no change had been made from the original design. When work is contracted for on a lump sum basis, there are invariably disputes over the detail drawings, extra work and changes, and these often have to be adjusted at the completion of the work by a Board of Arbitration. This is always disagreeable. Such bad conditions do not exist on any work that is contracted for on a basis of cost-plus-a-fixed sum.

5. "The owner or his representative has at all times full control of the construction." This has been shown in speaking of results one to four.

You will note that by this method we have eliminated the most important of the disagreeable factors which enter into ordinary contracts and we have embodied in this method many desirable features which do not exist in lump sum or percentage contracts.

All that remains to be said in regard to Cost-Plus-a-Fixed-Sum contracts is that we are extremely well equipped to handle work on this basis.

Yours truly,

FRANK B. GILBRETH.

BY THE WAY.

The wasteful mountain torrent in California and the arid land are being brought together by the aid of long-distance transmission of electrical power. The wilderness promises to blossom as the rose; for the dessicated fertility of these lands is of long accumulation and abounds with fruit under the simple influence of water. The water is there but beneath the surface so far that horse-power is required beyond the power of horses. Mountain streams have been used to supply power to pumps as much as a hundred miles away, and the Kern river is being, or has been, harnessed for the great orchard and farming regions, 125 miles away. This, though primarily a Californian affair, has, like most things now-a-days, a bearing upon our Imperial question. What is possible in California has excited attention in India as possible for India; except that there it is paddy and jowra and bajra that propose to lift their heads; and, though it is somewhat of a leap in the dark, we may affirm that it will be a good day for India when paddy prospers and jowra and bajra are within the reach of everyone.

× × ×

Excavations of foundations for two or three large buildings in the down-town district of Chicago will be made in a novel way. Chicago's down town streets, as now is generally known, are paralleled forty-six feet below the surface with tunnels corresponding to the streets above. In order to get rid of the earth from the building foundations the Illinois Tunnel Company, owning the underground tunnels, will extend spurs from their main tunnels to a point about the center of the lots to be excavated and wells will be dug connecting these spurs with the surface. Steel cars of about 20,000 pounds capacity are being built, which will be run to a point at the bottom of the wells, and earth from the foundations will be shot down the well into these cars. An outlet for the earth thus set below ground will be provided on the lake front, where the cars with their loads of dirt will be elevated up a well and run on tracks to the dump.

× × ×

The chairman of the London County Council has, in an opening address, been reviewing the work of the Council during the fourteen years of its existence. Among bewildering thousands of persons rehoused and millions of people carried over the Council's tram lines we meet with one figure that is a recognizable achievement: the death rate has decreased by 40 per 1,000. That is something definite and a great improvement. It is attributed to the clearance of slums, the building of better houses and the opening of parks and recreation grounds. There is no doubt that this attribution is right and it is encouraging. To support the intolerable deal of preliminary talk that is necessary to get public improvements done, particularly those which affect the welfare of the classes who do not or cannot concern themselves in the matter, it is necessary to have a clear consciousness of the certainty of results; otherwise the dread of becoming a Mrs. Jellyby creeps over the promoter and makes him flabby and irresolute. Here then is evidence that cleanliness, comfort and beauty are practical matters, and that the result is not only definite but so quick in coming that effort and expenditure to get and maintain these conditions is not over-altruistic.

CAMERA IN SCULPTURE.

Charles Boesse, who recently invented a new process of photo-sculpture which, according to the scientific publications, is destined to revolutionize the photographic art, has arrived in Rome, where he intends to start his first establishment. The young inventor was born in Florence; his father was German and his mother French. He is only 25 years of age and admits that he owes his discovery to chance.

He explained the way he is able to produce in relief all sorts of pictures by a very simple process. The fundamental principle of the invention lies in the discovery that gelatin, sensitized with bicromate of ammonia, loses the property of absorbing liquids in proportion to the length of time it has been submitted to the action of light. A cake of such gelatin immersed in a special liquid under a photographic negative will after a while show relief and depressions, representing the image on the negative.

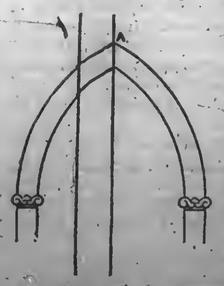
The difficulty in M. Boese's invention was to procure a negative in which the transparency would be proportioned to the degree of relief which it was desired to obtain. In order to do this the object to be photographed is placed in a dark room in front of a specially constructed camera and a special blue light, filtered through a red prism, is projected on it. Two poses are necessary, so that, having obtained the first impression, the operator rapidly reverses the negative and takes a second picture on the same plate.

This negative is developed like all photographic negatives and is copied on film, after which the two pictures are laid one on the other, and thus a negative is obtained totally different from the ordinary photographic negatives. If the cake of prepared gelatin, immersed in the special liquid, is exposed to the light under this negative in five or six hours it will reproduce the picture in relief with the utmost perfection of detail.

Mr. Boese already has given practical demonstrations before the Camera Club and the Royal Institution of London and the Urania Society in Berlin.—Toronto World.

AN OPTICAL ILLUSION.

The engraving represents a Gothic arch bisected at one side by a straight column, the apex of the arch being at A. On looking at the two sides of the arch, it will seem impossible that both can be of the same degree of curvature, or that the line of the shorter side, if extended, will join those of the longer. It can, however, be very easily proven by drawing two lines with a pencil across the straight bisecting lines, when the arch will at once appear in its proper form, although until this is done the eye refuses to perceive the fact, and the appearance of two dissimilar arches persists. This illusion is of practical importance to architects, who, in planning buildings with arches, should avoid placing columns in such a position that the arches will be unsymmetrically divided by them. — Popular Science News.



MONTREAL NOTES.

A number of new buildings are now in course of erection in the neighborhood of McGill University. The college buildings themselves are a somewhat disjointed and oddly assorted crowd, but the grounds with their grass and trees form a pleasant feature in the western part of Sherbrooke street—the only street in Montreal which one can be really proud of, and that more for its good surface and fine avenues of trees than for its architecture. There is reason to hope that in this latter respect also we may soon see some improvement. The space in the college grounds having become pretty well occupied with buildings, there now appears a tendency to expand along the farther side of Sherbrooke street. As the property here can probably only be purchased in comparatively small lots a less promiscuous and probably more severe and dignified placing of the buildings will have to be adopted. At the corner of McGill College avenue and Sherbrooke street the new McGill Y.M.C.A. building is now in course of erection from the designs of Messrs. Finley & Spence. The more important facade is of freestone, the other of brick. A little east of this at the corner of Victoria street excavations and foundations are in progress for the Students' Union Building.

Not far from these buildings in Peel street there has just been completed the shell of the new clubhouse of the Montreal Amateur Athletic Association from the designs of Messrs. Brown & Mitchell.

Much care and skill has obviously been brought to bear on the architectural treatment of this building. On a base of Montreal stone the walls are of brick to which the employment of irregularly scattered black headers gives a certain richness of colour. Freestone cornices and window dressings are used. A strongly Greek flavour has been given to the design generally and more especially to the details. Thus the openings are straight-headed—the ground storey is finished at top with a broad stone band with carved fret ornament; on this stand six flat and broad pilasters extending through the next two stories. A strong entablature crowns this range of pilasters and above the main cornice is a classical attic storey. The doorway in the center of the building of very simple square-headed form impresses by its size and depends for richness upon broad surrounding mouldings and simple cornice all carved with ornaments of a very pronounced Greek character.

One cannot help being a little afraid that the popular verdict on this building will be that it is a square factory-like block. Two circumstances militate against it. The first and most obvious is the tremendous extent of the wing elevations to which the treatment adopted to vivify the front has not been extended, and their huge inert masses have a deadening effect upon the whole, the more so that the street not being a very wide one the passer by takes his impression of the building from some distance along the road where one or other of the great flanks is well in view. The other circumstance referred to is the fact that the mass of the building is in brick—a material with a considerable degree of colour, therefore tending to detract from the force of a design of delicacy and intricacy because the shadows and high lights caused by slight projections and which would be obvious enough on a building all of stone become lost where the mass is of brickwork. Here, though it is somewhat beside the mark, one may recall the banded treatment of brick and stone used in many fine old buildings of Belgium and Holland—a treatment which restores to the eye the ability to follow not by the light and shade but in another and very charming way all the little "ins" and "outs" of a wall surface. In that case however the colour so far from being simplified is rather heightened and demands the adoption of architectural forms especially suited to that method of building.

Before leaving the fine building of the Montreal Amateur Athletic Association one cannot help wondering whether the jewels of Greek imagination can ever be set so as to appear a natural product of plutocratic materialistic Montreal.

At the corner of St. Catherine Street and Greene Avenue there is now almost ready for occupation the new branch of the Royal Bank of Canada designed by Messrs. Maxwell. This building has two facades of sandstone standing on a base of limestone. It is of no great size—the total height is probably less than 40 feet—but it arrests attention by its appearance of compactness and unity. Any one who finds delight in stones of generous size may contemplate this building with great pleasure. The courses of the masonry are 21 inches deep and the blocking course on the top seems about 3 feet deep. This with the general air of breadth and simplicity about the little building comes upon one like a breath of fresh air after having to fill one's eyes with so much of niggled and unwholesome tawdriness that swarms around. As might be expected from an architect with an appreciation of good stone the details, the cornices and the quaint Ionic capitals are worked out in careful and even recherche manner. The main doorway and large front window mutually

trespass on one another's domains in an audacious if picturesque way that must take the breath away from an ordinary law abiding citizen.

A little farther on in Green Avenue a small branch building of the Bank of Montreal has recently been erected by the same architects and shows the same quality and finish though not the same breadth and simplicity as the Royal Bank just described.

CONCORDIA SALUS.

Mr. W. C. Harris, A. R. C. A., architect, of Halifax, Nova Scotia, spent a few days in Toronto recently, en route to the World's Fair at St. Louis.

ADDRESSES AT THE OPENING MEETING OF THE ARCHITECTURAL ASSOCIATION.

The new president, Mr. Guy Dawber, made a long and useful address from which, as printed in the Building News, we make the following extracts, which are concerned with matters of interest to the profession in this country.

THE LAYING-OUT OF STREETS AND DIVERSITY OF DESIGN.

We are living in a wonderful age of building, when houses, streets, great towns indeed, spring into being almost in the space of days. In London, large schemes are in hand, such as no previous generation has ever known, and which are changing the character of whole districts. The most conspicuous feature in this new architecture is its entire absence of uniformity or consideration of surroundings. Architects, with varying success, have given rein to their imaginations without allowing themselves to be controlled or influenced in any way by neighbouring buildings; so that our streets present a want of character and scale which is singularly unsuitable in a city such as this. That this should be the case where many of the buildings individually are most admirable, is lamentable, and I cannot help thinking that it is a matter for regret that in this country we have no Ministry of Fine Arts, or some consultative committee on art who could advise when sites come into the market, or buildings are pulled down, as to the form the rebuilding should take, or what improvements or modifications in the design would conduce to the future dignity and beauty of the City.

It is, perhaps, too much to hope that the London County Council will control the capricious talents of architects and builders in Aldwych and Kingsway, but the greatest opportunity of recent years will be lost if such sites are allowed to be covered with individual erections—the creations of commercial syndicates, too varied in style and material to give any dignity or character to their environment. The recent changes in the Strand have proved that a great deal of the beauty of Saint Mary's came from the fact that the church was so well fitted in style and size to the position in which it was built, and to the height of the houses around it. I venture to think this essential principle is not sufficiently regarded in most of the new buildings we see on all sides. This feeling of inequality and lack of proportion is more noticeable in our street architecture than in anything else—there is no settled tradition in building; no definite aim or standard in view, and all treat different things in different ways, and the "loudest" and most garish edifice attracts the most attention. This, again, is emphasised in the treatment of our shops, where massive buildings, many stories high, rest with no visible means of support upon huge sheets of glass, whilst the facades of many others are covered and disfigured by enormous letters and advertisements. It is indeed strange that we should, as a nation with some claims to taste and refinement, tolerate these shams and eyesores that mar and spoil the finest streets of all our large cities and towns.

I cannot help thinking we have lost a good deal in the beauty and consistency of our street architecture since the days when such men as the brothers Adam, Chambers, Nash, and the Woods of Bath gave us their quiet facades and street fronts, all based on some definite idea and planned on a big scale, and though perhaps slightly uninteresting to us to-day, yet possessing dignity, scale, and symmetry. In street architecture the mass should be the main idea and the individual building should be subsidiary to the general design, but exactly the opposite seems to be the prevalent idea to-day, and one cannot help looking forward with some degree of misgiving to the result of such experiments as we see in Regent-street, which break the simple lines and grouping of what, however much its monotony may be abused, possesses some claims to design on a monumental scale.

Without doubt, all this variety, this diversity of idea and design which we see everywhere throughout the country, is attributable to our lack of architectural education in the past—we have not learned in any school, nor on any method, and hence our architecture, like our training, is individual and haphazard, everyone building what best suits his taste, just as our students study or pick up their ideas in a like manner. On the other hand, in essentially domestic architecture this country stands pre-eminent. Our country houses possess a character and quality of which we may well be proud, and in this branch of our art a common sense and legitimate use of material is producing a style that stamps the building of to-day. In municipal architecture we have also vastly improved during the past decade, and many of our modern buildings are well worthy of comparison with the works of masters of bygone years.

But as a nation we have quite failed to recognize the importance to the community of well-thought-out schemes of building and their environment on a large scale. We lack in England that spirit of civic pride which is so pronounced abroad—a pride in the beautifying of our cities and towns that makes one vie with the other in a display of noble buildings, dignified squares, and that co-operation of architect, sculptor, and painter, which alone can produce great and noble works of art. The least observant cannot fail to be struck by the feebleness of conception shown in dealing with the various sites that come into the market. It is deplorable that they should be regarded merely as commercial speculations, to be covered with buildings with neither character or individuality, and without the least regard for their surroundings, and perhaps more than anywhere else this is seen in the development of our suburbs. On the Continent this problem is dealt with in a systematic way, and the various municipal authorities prepare the lay-out of the general scheme, the lines along which the extension is to take place and the proportion of the whole site which may be covered by buildings. It is a great pity that our English town councils do not study the admirable work of town extension now being done in Germany, and do not obtain Parliamentary powers to do similar work here; our towns might then be developed and improved on broad and dignified lines instead of the haphazard way we now deal with a question that is worth far more consideration than is given to it.

Experiments have been made in recent years in this country, of building and laying out towns and villages on some artistic basis, and with very satisfactory results. The paper that was read last session on the Bournville settlement, showed that these buildings could be erected to pay a fair return of interest for the outlay, and entirely disposed of the fallacy that to build artistically is more expensive than otherwise. There can be no doubt that the influence of communities such as these must eventually have a great effect on the taste of the public. But unless this question of the extension of London suburbs is dealt with on some such lines, we shall be surrounded by a belt of appalling monotony and ugliness, as every suburban extension makes the existing suburbs less desirable.

ARCHITECTURAL DESIGN.

Gentlemen, all these are broad questions not unworthy of your careful consideration, and though they may appear to our younger members as dry and uninteresting, it is essential that they should be conversant with such matters, which in after years will force themselves on their attention. But do not believe that architecture has vanished as the pessimists say, for at least we are not satisfied with its substitute, and though houses and costumes perhaps fall short of mediæval grace and color, yet both are tending to become more seemly and convenient than those our forefathers knew. Slowly, but surely, we are striving for, and I think arriving at, that combination of beauty and utility wherein lies the truest, perhaps the only true art, and we have to-day an ever-increasing body of able and thoughtful men, who are doing work that is worthy of our highest admiration, and which is awakening the interest of the public in an art which for years past has been regarded with comparative indifference. In architecture, decoration, and the plastic arts, there is a strong and virile movement permeating the country, not only to treat material sensibly, but with freedom from the fetters of bygone schools of design. It lies in your power to forward this movement, to train your hand and eye, to study and labour in the profession you have chosen, remembering always that as the coming generation of architects with you rests a great responsibility. I would have you think of architecture from a national standpoint as a great power, and make up your mind from the day you enter the profession to devote yourselves to the uplifting of the noblest of all the arts. Your work will be your greatest recompense, and if you throw your heart into it you will find it a never-ending pleasure and engrossing pursuit to the end.

Look at things largely and try to think in the mass, and do not design your buildings as separate elevations, but picture them in the round, as imaginary buildings, that you can feel and handle, and plan out the surroundings, and the environment, so that the whole is complete in every way. If you accustom yourselves to this habit of thinking of your designs as a whole, you will be surprised at the grasp of idea it will give you and the increased pleasure you will get out of your work. Study the work of our best living men whenever you have the opportunity, as well as of those long since dead, and do not neglect the prosaic present for the picturesque past.

Whenever you see a beautiful building or work of art, either one just completed or an old one coloured by the mellowing hand of time, one that instinctively impresses you by its sense of proportion and fitness, try and analyse it and find out what it is in its conception and construction that produces this effect. The cultivation of this habit of analysing everything you see, of dealing with actual existent facts, will help you to design and plan far more than studying books and illustrations.

The reason we admire old work so much is, I think, partly sentiment and partly because it is, as a rule, thoughtful and honest—there is a feeling of reposefulness, of satisfaction and charm that so much modern work misses, and it is this spirit, this intangible something that one feels but cannot express in words, that you should strive to attain and which will give character and beauty to your work. It is the spirit and the thought behind the design that makes a beautiful building, and the more thought you put into your work the better and nobler will it be.

SKETCHING AND MEASURING.

In these days, when travelling is so easy, you should take every opportunity of studying and comparing in each country you go to the different ways in which similar problems are treated, and the materials and workmanship with which they are carried out; this will broaden and enlarge your mind, and you will gain many valuable lessons in design and construction. But do not sketch or measure with the object of copying old forms and features, for mere servile imitation is a sure sign of decadence and lack of creative force. At the same time avoid going to the other extreme, and in your efforts after so-called originality becoming "banal" and grotesque. Guard against being carried away by the love of the pretty and picturesque, the passing fashion of the hour, and recollect that eccentricity is not synonymous with genius. Do not worry over trifling details, trivial mouldings, and such things; the greatest and noblest buildings and those that impress us with their breadth and dignity, as a rule, are very simply treated. You know that ornament must follow good construction, and that this again must be based on the proper use of material, and, though the tendency of the day is to try to be original, to produce something fresh and striking, yet I venture to think, and indeed hope, that much of what we see around us is only ephemeral and will not hold its place in years to come, as representative of our architecture to-day.

Beauty in architecture does not result from richness of material and profusion of ornament, but from elegance of form and proportion, harmony of colour, and perfection of execution; and in a large measure from the intelligent application of material to its proper purpose. Many do not sufficiently remember this, and forget that all materials have their limitations and uses; so consider well the suitability of your designs to the materials you would build them in. Details and features that are right in one are wrong and out of place in another. It is unnecessary to urge you again to err on the side of simplicity and restraint in your work. Everyone can crowd his design with meaningless ornaments and detail, but few have the power of being able to know exactly what to use and what to omit. This can only be gained by careful study, by thought and experience, and though at times you may get discouraged and feel that your work is at a standstill and you are not improving, yet this very dissatisfaction may be the means of benefitting your work in the future.

THE FUNCTION OF AN ARCHITECT.

I cannot help feeling that if a man means to be an architect all his time and thought must be concentrated on his work and in that direction alone, and to attempt to make himself master of any of the subsidiary crafts, to work with his own hands on buildings of his own is a mistake. I have never been able to ascertain that

any of the greatest architects of the past were craftsmen in the sense that we use the word to-day, and I do not think that any work in any of their known buildings can be pointed to as actually executed by them. The function of an architect should be to design and have the control of the entire building, to be the master builder in fact, and to be conversant with all the work being done. He should, as far as possible, have a knowledge of the technique of the various trades and crafts, and be able in a general way to direct and control them all, but more than this seems unnecessary. To concern himself personally with matters of actual craftsmanship must be to the detriment of his buildings, because an architect cannot carry out the multifarious duties required to-day and find time to do these things as well; though of course if an architect wishes to work with his own hands, and has a tendency that way, he will doubtless produce excellent results, but the idea in buildings of any magnitude or importance seems out of the question. Do not be led astray by theories such as these, but try and gather round you artists and craftsmen in the allied arts, who understand and sympathise with your aims and who will work with you. That is what all our great architects have done and what we should try and do to-day.

The president was followed by Mr. Aston Webb, a former president of the Association, and recently president of the R.I.B.A., who, among other remarks, made the following additions, as reported in the Building News, to the remarks concerning sketching and laying out cities.

In his student days, when they entered a church they looked at the door, took a sketch of the jamb and the arch moulds in order to send a little drawing to the Architectural Association Sketch-book; when they went inside, if there was a screen they took a sketch of the carving and perhaps one or two of the mullions, and generally looked out little bits which would form an easy and useful little sketch. Very often they missed perhaps the whole interest that the church may have possessed, as he was thinking the other day when he was in a west-country church. He noticed, what was to be seen in many west-country churches, that the nave and chancel were of the same height; but, what was not so often the case, the transepts were also the same height, which gave the architect the opportunity of putting a barrel ceiling over the nave and chancel, and also over the transepts, so getting a groin at the intersection over the nave; the arcade was continued straight through to the chancel arch, but the wall was not carried up to the roof, so that one saw the roofs of the transepts over the arcade, giving a delightful and unusual perspective effect. What they wanted to teach students to see and understand was the scheme of the whole thing; the detail was a matter as to which the individual feeling and character of the man who designed the church should be left, to a great extent, unrestrained. Students would learn more from the general design and scheme of the architect of buildings visited rather than in looking at small details—mouldings, carving, and such like. The President had touched on another subject in which he (the speaker) had taken much interest, i.e., the desirability of some control, or some advice, in the laying out of towns and cities—both new and where great alterations are in hand. The subject had been sympathetically received by the present First Commissioner of Works, and it was quite possible that, if the profession supported the idea, that in time something of the kind might be obtained. They all regretted the stage in which the matter of the great new street of the London County Council stood. There was the competition for the selection of a design, the design was selected, but then no further action had been taken upon that. That was a matter of great regret; and, although they all knew that the London County Council were anxious to do the best, he should like to see some expression of opinion among architects that more decisive steps should be taken before it was too late to prevent that great street being built on in the style described in the President's address. During the last two years an important Commission had been sitting in reference to streets and traffic, and, as far as he knew, only one architect had been called to give evidence, and, as far as he could gather, the evidence of that one witness gave more suggestions than nearly all the others put together on the general lay-out of a city. It might be an ideal scheme, but it had the germ of an idea, i.e., radiating roads from London to the suburbs which would, to a great extent, redeem London from that monotony and dulness which the president had so properly objected to. He had always thought it is a most unfortunate thing that the municipal bodies of the cities and towns of England had dispensed more or less with architects as their advisers, and had engaged surveyors instead—absolutely necessary gentlemen in certain work; but, after all, in the formation of new streets, etc., there was something more required than the convenience of traffic and excellence of drainage; there was the question of æsthetic appearance, and the man who could give the best advice on that was the man who had been trained in such matters, and he was, generally speaking, the architect.

TORONTO ARCHITECTURAL EIGHTEEN CLUB.

At the annual meeting of the Toronto Architectural Eighteen Club held on October 11th, the following officers were elected: President, Mr. Henry Sproatt; first vice-president, Mr. E. R. Rolph; second vice-president, Mr. J. C. B. Horwood; third vice-president, Mr. C. D. Lennox; secretary-treasurer, Mr. J. P. Hynes.

STRENGTHENING A RETAINING WALL.

A dry stone retaining wall on the Albula Railway, Switzerland, built in the spring of 1902, gave trouble by slipping and was reinforced in an interesting way. Settlement was anticipated, and so the wall was built a foot higher than the intended level of its top. Several slips occurred during construction, attributed to the water flowing along the surface of the rock, and soon after the wall was finished it was observed to be creeping down and bulging out. In November the top of the wall was rebuilt. It passed the winter well, but the spring thaws and rains caused a renewal of the movement. At the same time the wall bulged badly in places and assumed a stronger batter than it had when built. To give the dry stone wall a secure foothold, as rapidly as possible a number of shafts were sunk down in front of it to reach the rock, and pillars of masonry made in quick-setting cement mortar were built up under the wall base, and also some way up in front of its face, being bonded into it as well as possible, to stiffen it against the bulging tendency. These buttresses of masonry were anchored into the firmer strata of the rock. The work, which had to be carried out with great caution so as to avoid any breakdown of the wall, was done in the course of three weeks, and gave satisfaction, as no further settlement was observed.

NORTHWEST NOTES

THE UNION BANK.

Work on this building, of which an illustration was published in our October number, was commenced on the 17th of October, 1903. 21 concrete caissons used in the construction of the foundation taken down to 40 feet below the sidewalk were used. These caissons average about 5 feet 6 inches in diameter, enlarged to about 12 feet diameter at the base. The steel work was proceeded with during the winter and was completed on the 5th May. The masonry including all brick work, terra cotta, etc., was started on May 14th and was completed on July 16th. From that date the numerous other trades completed their different works and the building was ready for tenants on November 1st. The banking room quarters will be ready shortly.

The building comprises eleven stories and rises to the height of 150 feet above the sidewalk level. The front is constructed of white terra cotta and buff pressed brick. The floors and partitions throughout are built of hollow tile, the floors being finished in maple with quarter cut oak and mahogany trim. All floors for public space in banking rooms, halls and corridors are of marble.

On the ground floor are the banking room and manager's office. The former is 48 x 72 feet in size with 28 feet ceiling. The principal entrance is from Main Street.

The windows in left wall and in west wall which faces Leland Hotel, have metal frames filled with wired glass.

The building is equipped with three fast elevators and is heated with steam, with vacuum air system for radiators.

Messrs. Darling, Pearson and Over were the architects and the Thompson-Starret Co., of New York, the general contractors.

WINNIPEG BUILDERS' EXCHANGE.

The Winnipeg Builders' Exchange held its annual meeting on the 8th inst., which proved to be a well attended and successful one. The Exchange continues to prove its usefulness and find favour amongst the building fraternity of the city. Seven new names were added to the roll of members.

At this meeting many matters of interest were considered and important business for the Exchange to deal with during the coming winter was broached by the president. During the long winter evenings it was felt that the social side of the Exchange should receive more attention, without detracting in any way from its primary function of a business organization. The remarkable success in this direction of some of the exchanges to the south of the line was adduced by several speakers from personal experience. The Property Committee was asked to confer on this matter and to lay some proposals before the Exchange at its next meeting.

Notice of motion was also given that two regular meetings in each month be held in future instead of one as heretofore.

With almost a month of beautiful Indian summer weather the building outlook has improved rapidly for the coming winter. Contractors say the fall has been most favorable for finishing their work, and very few buildings are not roofed in and ready for severe winter weather, should it come suddenly. When once the roof is on the buildings can be kept warm enough for the men to continue their work. Contractors have been rushing their work to reach this point and have succeeded.

On November 1st the new Union Bank building was thrown open to tenants and already the offices are nearly all occupied. The ground floor and first storey are given up to the banking business and its officials. This part of the building is not finished yet but is being pushed as fast as possible. From the third floor to the ninth inclusive is occupied entirely by offices. There are thirteen suites on each floor, these again being divided into different compartments to suit tenants. On the tenth flat are the lavatories, janitor's quarters and rooms for the janitor's staff. All work is finished in hardwood and thoroughly up-to-date throughout.

The new Liberal Club on Portage avenue is rapidly nearing completion. This is a three-storey building with basement. The front is of Redford stone and hydraulic-pressed brick, giving a soft grayish appearance. The ground floor is for the club room. It is 42 x 70 feet and has a large plate glass front with tiled entrance. On the second floor is a large committee room and a number of bachelors' apartments with bathroom in connection. The third floor consists entirely of bachelors' apartments. It is expected to be ready for occupation early in 1905. Mr. J. Chisholm is the architect.

Pilkington Bros., of St. Helens, England, are having a large warehouse built on Market street east. This building will be 100 x 100 feet, four stories and basement. The foundations are being put in but it is undecided as to whether the work will be pushed through the winter or not. S. F. & W. A. Peters are the architects.

Another new building that has just been commenced is the Grundy block, on the corner of Portage avenue and Hargrave street. This block is to be 88 x 130 feet, four stories with basement. It is for stores, offices, etc., and will be carried on during the winter.

The new O'Connor hotel on Notre Dame street east would have been roofed in by now but that it has been decided to add another storey to it, making it five stories. It will contain about seventy-five rooms and be up-to-date in every respect. J. Cadhow is the architect and P. Burnett the contractor for the masonry.

The old Assiniboine block has undergone a great change. It has been remodelled and will now be known as the Empire Hotel. It has a frontage on Main street of 150 feet, which has been filled with large plate glass windows, 6 x 12 feet in size. As rearranged the building will contain about 200 rooms, comprising single rooms and suites, each with a bathroom in connection, and finished throughout in first-class style. A. & W. Melville are the architects for the alterations.

The new theatre is being rushed to completion, as it is the intention to open it by December 5th. This building is being done by Frank McClure, of Chicago, theatre builder. The front is of cement block, manufactured by the Canadian Petrified Stone and Brick Company. The building has the usual balcony, gallery and pit for seating and will hold about 1,200 people.

Work on the Agricultural College has been commenced, but it is not likely that more than the excavating will be done this season.

Plans for the new Normal School on William ave. and Francis street have been prepared by Mr. Hooper, government architect, but nothing will be done this season.

The Land Titles offices and the Carnegie library are both roofed in and the inside work is being pushed.

The work on the new C.P.R. station has been pushed very vigorously and the station part, baggage rooms and offices, are expected to be ready for occupation by the first of the year. These buildings will be four stories high with a basement. A temporary roof has been arranged so that the lower portion for offices can be finished and the staff take possession, as the old building has to come down. Most of the plastering has been done, no lathing being required, as a plaster board has been used and the rough and smooth plaster put onto this. The radiators have been arranged in a temporary fashion so that steam may be turned on when necessary. The hotel proper is not so far advanced, but already the foundation walls have been built, the concrete bases for the steel pillars laid and a number of the pillars placed. The hotel is to be a seven-storey building with about 350 rooms, and will be the largest and most complete and up-to-date hotel in the West.

This month the Main street subway was opened to foot passengers and hundreds of people traversed it to see the work. By December 1st it is expected that the whole street will be opened and the street cars running through to the north end. This is a very fine piece of work, and, although to the eye it appears to be all concrete work, in reality there is enough steel and iron worked into it to almost carry the whole strain of traffic from the the cars. Steel trusses are run parallel with and under all the tracks, and these again are supported by iron rods running into

the concrete pillars and platforms to carry the strains from the arches. The concrete pillars have steel and iron trusses running through perpendicularly. They are built on cement and concrete piles. Cover, foundation and all the arches and pillars are held by a network of steel and iron bars. The sewer pipes, etc., in the street were all removed from the centre and re-laid on either side and the platforms and subway are thoroughly drained. Pipes carry the drainage into the Point Douglas sewer and this sewer is again drained through under the hotel into the higher sewer on Fonseca street, so that there is no danger of water backing up in the spring. The subway in the daytime is lighted by twelve sky-lights in the arches, fitted with prism glass; at night, by electric lights at the intersection of each arch. There will be 38 lights, controlled by a time-switch arranged to light up at any desired time and to run one week without being attended to. The street car track has 18 inches of concrete beneath it, and the balance of the road about six inches, surmounted with cedar block pavement.

The Bell Telephone Company's new addition on Portage ave. east has been roofed in and inside work will be done as soon as possible. When the present alterations and additions are completed the Winnipeg Telephone Exchange will have a capacity of 10,000 customers. New switchboards are to be put in as soon as the building is ready to receive them.

Quite a large number of fine residences have been built in Winnipeg this season; some costing $50,000, and quite a number ranging from $15,000 to $30,000. From time to time we hope to be able to print illustrations of a number of these houses.

The J. H. Ashdown Company, Limited, have commenced to rebuild now they have got the rubbish cleared away after the fire of last month. They intend putting up a fine retail store, but all the plans are not completed yet.

Bullman Bros., whose new block was destroyed by fire last month, have already got into their new premises—a large frame building, 100 x 120 feet, on McDermott ave. Mr. J. Bullman undertook the planning and rebuilding, and everything was done by day-labor. They intend making their own power for electric light and will run all their machinery by electricity.

The Portland Cement Company, of Manitoba, have received letters patent to manufacture Portland cement. The company is capitalized at $1,000,000. Head offices will be in Winnipeg and works at Springfield. They will have two units of machinery in operation in 1905 and will install another four units later, making a 1,000 barrel mill. The cement marl is said to be of a very high quality, and as this material is now being used for so many purposes in the building line, no doubt the company will find a large market for it through the West and will be able to put it upon the market at a reasonable figure as it is being manufactured right at the door of Winnipeg and the West, as it were.

Herbert H. New, architect, has removed his office from Main street to 928 Union Bank.

G. H. Archibald, C.E., has removed from the Merchants Bank to 820 Union Bank

Herbert R. Rugh has removed his office from 367 Main street to 927 Union Bank.

BUILT ALL IN A DAY.

The unusual feat of building a five-room cottage, including foundation, plastering and putting on one coat of paint, in a day of 10 hours, with a cost to the owner of nothing more than a chicken dinner for the workmen, outside of the material, was performed in the little hamlet of Maple Grove, near Evansville, Ind. The man for whom the cottage was built is Homer Rose, and the men who did him the kindness were fellow-employes. The work was superintended by Dee Bacher, a contracting carpenter.

Mr. Rose had had lumber and other material on the ground for months. After these were bought he discovered that he could not go on with his house for lack of means. Mr. Bacher called his men around him one evening and asked for volunteers for one day to build the Rose cottage. Many thought it would be impossible to build it in one workday, but the contractor declared that he could accomplish the feat if the men in his employ would do the work. Twenty-six carpenters, masons and painters agreed to give one day if Mr. Rose would furnish a chicken dinner, and a time was fixed when all should report at the site of the proposed building.

Every man appeared on time. The brick-masons went to work laying the foundation, while the carpenters busied themselves in cutting the joists, studding and sills. Every man was assigned to a particular part of the work, and the house began to go up in a rush. Hundreds of persons gathered about and watched the workmen. Each of the latter urged his fellows on, and when noon came the frame work was all up and the chimney had been started.

Then came the dinner. Mrs. Rose, assisted by some of her neighbors, had fried two dozen chickens. There were 10 loaves of bread, four dozen ears of boiled corn, nearly a bushel of mashed potatoes and bowl after bowl of gravy. The dessert consisted of peach cobbler and various kinds of pies. The contractor had to call off his men for fear that they would eat so much that they would not be able to finish the job.

As soon as the frames were set for the windows and doors the sashes were fitted and the lights put in. By this time, however, the laths had been put on inside, and the sheeting and weatherboarding were being placed on the outside, and the chimney was being run up by the masons, all at the same time. Before the roof was on the plasterers were at work, and exactly at 6 o'clock the cottage was finished, all but the second coat of paint and the skim coat of plaster, neither of which could be put on before the first coat had dried.

Mr. Bacher complimented his men when the job was complete. He said that while he had done some "hurry" work in his time, he had never known a house to be begun and completed in a day. The cottage contains five well-lighted rooms and a large attic. Everything, even to putting on the hinges and locks, was done before the men were called off at 6 o'clock, and Mr. Bacher declares that he could have completed the work an hour earlier had not the men eaten so freely at dinner.—Architects Builders Journal.

DYNAMITE IN GREAT FIRES.

When all other means have failed to check the progress of an extensive and destructive fire it has always been the custom to demolish buildings in its path, in order to deprive it of fuel. Of late dynamite has been used for this purpose, but we are now told by an editorial writer in Engineering News that, as a result of experience in the Baltimore and Toronto fires, this means of checking the spread of conflagrations will probably occupy a less prominent position in the future, as it is apparently not only useless, but positively dangerous. Says the writer:

"In both cities the effect of the explosions on the ruined buildings was simply to produce a heap of wreckage which could not be mounted by the firemen, and which was scarcely less combustible than the original building, while the gap placed in the path of the flames was so narrow that it was easily leaped by the fire. The effect on the surrounding buildings, which it was the purpose of the explosion to protect, was to smash in the windows and thus destroy the only barrier that existed against the immediate penetration of the flames to the interior combustible finish and contents. In the case of some of the fireproof buildings at Baltimore there seems reason to believe that a considerable part of the damages to the walls and to the structural fireproofing was caused by the violent shocks produced in dynamiting adjacent structures. However this may be, it is certain that in many cases the dynamiting was delayed until the 'mined' building was ablaze, with the very natural result that burning brands and debris were actually hurled through broken window openings into neighboring buildings. Such happenings as this are, of course, chargeable solely to unwise direction of the work, but they are certain to occur in the excitement and panic of a losing battle against a conflagration. At best, dynamiting is a dangerous and uncertain means of fighting fire unless it has been much maligned by the experience at Baltimore and Toronto, and heads of fire departments will act wisely if they strike it off their lists of fire-fighting methods."—Architects & Builders Journal.

A Croydon builder was recently fined £2 and costs for using bats instead of bricks for the walls of two houses. In one case there were eleven whole bricks where there should have been sixty, and in another piece of work there were forty-eight bats to one stretcher.

The great man is the man who can see how things are going. How far he is also a successful man in his own generation depends upon how far he sees how things are going in his own generation. To know what will happen is no doubt great, but it is sometimes even greater to know what is happening.

SUGGESTIONS FROM NEW ZEALAND ON THEATRE PLANNING.*

The following is an abstract of a paper read by Mr. S. Hurst Seager, architect, of Christ Church, New Zealand, at the Australasian Science Congress held in January last at Dunedin. The abstract of the paper was forwarded to us along with the accompanying diagrams. The paper had special reference to the provision of exits and escapes at theatres and places of amusement. No more important problem presented

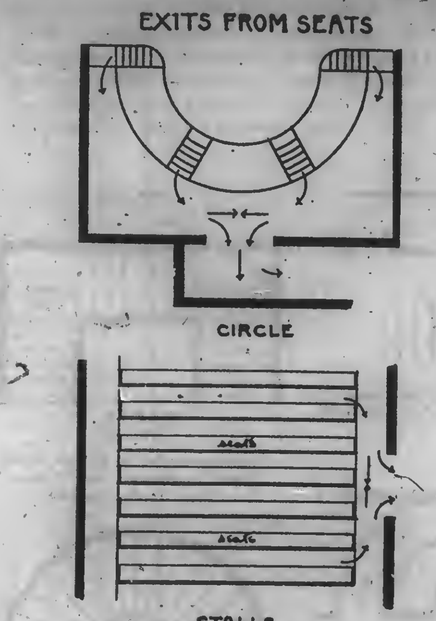


Fig. 1.

itself to the artchitect, said Mr. Seager, than this, yet there was none which he had less successfully solved. The problem was not to design a building in such a way that a an audience might leave it without discomfort under ordinary circumttances, but to design one which would be free from danger in times of panic, arising either from alarm of fire, earthquake, or other cause. It had to be borne in mind very clearly that the problem was not to be solved by demanding on the part of the audience a certain course of action under any unusual circumstances, for at that time they were incapable of thought and incapable of determining what action to take. The problem therefore was to plan a building which should be so arranged that without choice irresponsible people would be compelled to move in a certain direction, and that that direction should be absolutely free from all resistance. Without resistance there could be no pressure; without pressure there could be no danger. It was the neglect of this fundamental principle which had been the cause of such sad loss of life in the past, and its continued neglect would be responsible for all that took place in the future. The first impulse of most of the audience at the time of imagined danger was to rush from their seats towards the entrance from which they approached (see Fig. 1). That at once made it perfectly clear that the usual entrance must in all cases be the exit, and safety did not depend at all upon any number of so-called special "escape doors." These were simple delusions, and should not be provided. There must be entrances, carefully calculated as to number and width, leading to different parts of the building, to be used both as entrance and exits for that part only, and the greatest care should be taken that each entrance should give uninterrupted communication between that portion of the building for which it was designed and the open street. It could not be too firmly insisted upon that there must never be any connexion whatever between one corridor of communication and another. Each entrance and exit should be perfectly independent of all others. To carry this principle out fully every building of entertainment should stand wholly detached with sufficient space round it to prevent any chance of blocking. Very many Continental theatres were so placed, and most decidedly no new building should be licensed which had not a perfectly free, even space on at least three sides.

These spaces should be kept free during a performance. Carriages should always be drawn up sufficiently far away to allow of a free rush of people from the exits, for a very great source of danger existed in allowing carriages to stand on the edge of the pavement directly opposite the only means of egress. Gutters just opposite and steps just outside entrances were also sources of danger which should certainly be got rid of. Special provision should always be made for those using conveyances, so that they could reach them without interfering with the flow of foot traffic or of being inconvenienced by it (Fig. 2). In order to avoid any resistance in passing from the seats to the corridor or doorway, provision should be made so that the streams of people approaching the doorway from different directions could be directed through it without conflict with the opposing streams. This could be affected by means of curved barriers, which he had designed (Figs.

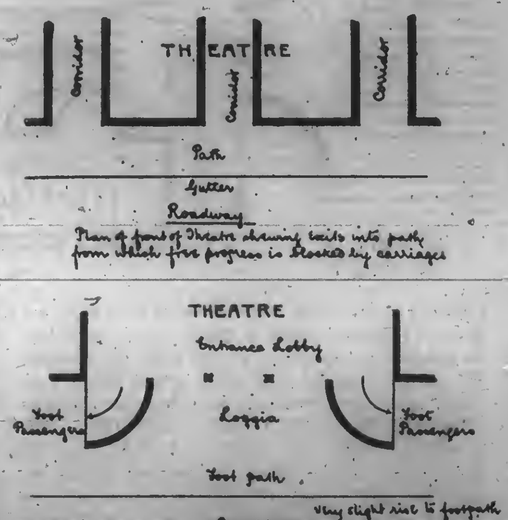

Fig. 2.

*From The Build

3 and 4), arranged so that any pressure exerted by the people behind would force those in front not against other people, but only more quickly out of the building. The seats should always be fixed, and the rows should be a sufficient distance apart to enable persons to walk easily between. Then the corridors should be of even width throughout, perfectly smooth, and any change in direction should be made by curved surfaces. The sum of the widths of the openings into any corridor should not be greater than the width of the corridor itself, and the stream of people entering it through any opening should be prevented by barriers from interfering with the progress of those entering it through other openings, for the greatest danger existed in allowing a stream of people to enter a corridor at right angles to the stream of people already pressing along it. Sliding doors into corridors should never be permitted, but all doors should be hinged to open in such a way that the progress of a stream of people pressing outwards will not be impeded. Staircases should be of even width, and designed with curved surfaces as corridors according to the London County Council rules. The steps should be of equal width throughout, and the flights should be easy, of equal length, and contain no more than eight steps. His own experience led him to the conclusion that easy steps, built in a staircase of even curvature throughout, were much more safe (Fig. 5). Either form might be safely used, but irregular stairs of any kind should be strongly condemned. All stairs and corridors should be of fireproof material. For the walls, steps, floor and ceilings, events had proved it much more essential to safety to scientifically design the entrances and exits that insist on fireproof construction throughout. The lecturer also drew attention to the danger of loose chairs for sitting accommodation, as they impede the traffic in leaving a public place of entertainment. In conclusion he moved :—"That this section of the Australasian Association for the Advancement of Science is of opinion that places of entertainment and public assembly, in order to be considered safe against the dangers arising from panic, must be designed in accordance with the principles here set forth and shown in the accompanying diagram."

It was decided to refer this resolution and the following to the consideration of the General Council :—"That the Architectural and Engineering Section of the Australasian Association for the Advancement of Science, recognising the urgent necessity for the planning of all buildings used as places of entertainment and for public gatherings in such a manner that the safety of the public may be ensured, wishes to bring before municipalities the principles upon which such works should be designed, as embodied in the foregoing resolutions, and would urge that a license be not granted to those buildings which do not fulfil the conditions stated, and that a copy of the above resolutions be forwarded to all Australasian municipalities."

THE NORMANDIN CEMENT BLOCK MACHINE.

The hollow cement building block is fast becoming a most popular building material. Every year sees a decided increase in the number of buildings erected in concrete, and the severe fires which we have experienced have done a great deal towards the development of concrete building construction, as it is well known that concrete is to a large extent fireproof.

The Cement Building Block Company, of Winnipeg, report having used and sold over 7,000 barrels of Portland Cement in seven months. They have had five block machines at work constantly in Winnipeg and established over thirty complete block yards through the West this year.

The demand for the Normandin block machine in Ontario has been so great that the Cement Building Block Company has opened a branch office at 42 Yonge Street Arcade, Toronto, where the machine may be seen at any time, also samples of the work done upon it. We are informed by Mr. J. A. Hunter, president of the company, that the Normandin machine is now in use by the United States Government, which should be a sufficient recommendation. The work is neat and of great variety of design and shape. The machine is easily operated by hand. They are made at Walkerville, Ontario, and Jackson, Michigan.

SPECIAL CONTRIBUTORS.

MR. W. A. LANGTON, Architect, Toronto.
" EDMUND BURKE, " Toronto.
" S. H. TOWNSEND, " "
" Prof. Percy E. Nobbs, Montreal.
" FREDERICK G. TODD, Landscape Architect, Montreal
" W. H. ELLIOTT, Toronto.
" A. F. DUNLOP, R.C.A., Architect, Montreal.
" FRED. T. HODGSON, Architect, Collingwood, Ont.

Sir Aston Webb.

Honours bestowed on the occasion of the King's birthday, last month, included knighthood for Mr. Aston Webb, R. A., the late President of the Royal Institute of British Architects. He makes the fifth Knight in the profession in England. There is also a Baronet.

A Skyline of Tanks.

Toronto, since the fire, has come to the conclusion that there is nothing so satisfactory for the business part of a city as a general use of sprinklers. That is agreed. But how about the tanks which crown the buildings thus equipped. The cooper's art is one of our few surviving handicrafts, and it is right we should exalt it—but abstractly. This elevation of a monstrous vat to roost on every building is grotesque; fine in its way, but not in the way in which the town aims at being fine. If we had mill design as well as mill construction the ensemble would be perfect, but we are in the grip of the Renaissance and must be Renaissance all through. Fortunately, though a Renaissance tank would tax the resources of Vignola, a Renaissance tower is easy, and, if clients require precedent for a tower on their buildings, there is one at home in the Canada Life Building. The low tower which is the making of that building has for its *raison d'etre* the elevation of a water tank to supply pressure to hydraulic elevators. The Canada Life tower was carried out on a scale beyond absolute requirement, but it suggests, on whatever scale, the architectonic solution, for, though, a sky line of tanks is absurd, a sky line of towers would be quite another thing.

Engineers for Fire Chiefs.

One more department of modern life is about to get into the hands of the engineers. The case of the Flett-Lowndes' building in Toronto, where, after the fire which started the sprinklers was extinguished, 20,000 gallons of water were sprinkled on the goods, because the firemen could not find the valves which controlled the service, points to new conditions that have to be met. In the first place the headmen of every district must be (and in fact are) informed of the position of the valves of every automatic service in their district. But they must remember where the valves are, or have a note of it in such form that they can refresh their memory in a moment; and, as the simplest form of note and the most quickly read is a plan, there should be a plan of every automatic system in a given district filed at the district fire-station. And the station-boss should take the plans with him to every call in his own district, to guide not only himself but the chief. Secondly the firemen must be familiar with the mechanism of all such contrivances. At the Flett-Lowndes fire they appear to have wasted time in experiments from want of a clear understanding of the functions of the pipes connected with the sprinkler system. And an insurance man declares that, when h

attempted to explain a system newly installed to some members of the fire-brigade, he could not get them to understand it. So the brigade, or at any rate the bosses, have some new ideas to get hold of; which no doubt they will do by practice. But amid the fire appliances, the preventive appliances, and the construction and mechanical equipment of buildings, the chief wants a good deal of technical knowledge, and public opinion is turning in the direction of an engineering qualification for this office. Among the deductions of Mr, Edwin O. Sachs from the reports on the Baltimore fire (discussed in another column), is "The necessity of officers in charge of fire-brigades having a technical, i.e. either constructional or engineering education of a high standard."

Censorship of Buildings.

Mr. John Belcher, in his opening address as President of the Royal Institute of British Architects, advocates the establishment of public censorship of buildings. He would have the First Commissioner of Works act as a minister of fine art with the aid of an advisory committee, and possess despotic power to decide what may and what may not be done in the treatment of public places and the spaces and buildings around public institutions, in the formation of new thoroughfares and in the question of buildings har monizing with an existing or determined genera scheme. A building act, Mr. Belcher says, can determine heights and so on, but no act of Parliament can define the subtle qualities and delicate *nuances* which make the difference between art and lack of art.

This is very true, and in England it is possible to find not only First Commissioners of cultivated taste but also an advisory committee which may be trusted to be as expert as the expert whose work is in question; so that on the whole there is a greater safety in giving authority to a combination of this sort than in giving free sway to individual indifference or extravagance or even to individual good taste; for a standing commission would be the means of maintaining what is the greatest deficiency in modern streets—unity of style. The greatest thing in a street arcbitect is harmony. A high level of taste in one manner (we are assuming a high level) is better than a jumble of motives, even if here and there (and it would be only here and there) it touched perfection. Mr. Belcher seems to derive support from the United States, where, he says, "some such exercise of authority has been found necessary." If this means the municipal Art Commissions, they hardly go as far as Mr. Belcher proposes, but to judge from some newspaper utterances they are a success as far as they go. Their power is only one of veto, but this is a great power; for no one, whose work has to come before the Commission, wishes to run the chance of crowning his labors with a veto. He does some wholesome vetoing himself as the work progresses. This, which is the process of all good design, is thus forced upon aspirants for municipal work who, before the appointment of an independent commission might have trusted to political influence to carry them through.

Models in Staff.

Anxieties about the result of altering the east front of the Capitol at Washington have drawn from the Mr. W. S. Eames, President of the American Institute of Architects, a suggestion that a full-size model of the proposed alteration should be erected. The cost is estimated at $100,000, and it is thought worth while to go to this expense although the scheme of the architectural committee's advisors, Messrs. Carrère & Hastings, is presented in the form of a model and there is another scheme of which a model is also provided. The contention is that a small size model is so completely grasped by the eye that it may mislead as to the actual effect in the case of a large building or one with a limited range of distance for points of view. All architects, no doubt, meet occasionally with unpleasant surprises in their executed work, but the conditions under which the work is done have much to do with that. In the case of the Capitol the conditions—a complete model to show the design, an existing building to help the eye of the imagination in judging the effect when completed, a stereotyped style which has few surprises for any architect and can have none for the firm advising the committee—all these conditions make so much for certainty in the present case that it gives an emphasis to this public confession of architects (for Mr. Eames fills a representative place) that the only result of the high development of architecture during recent years in the United States is to make the profession tread with fear where an earlier generation went confidently on. It is not a stimulating position. Is it really so impossible to conceive the effect of a design from the usual aids—drawing, modelling to scale, helped occasionally by a full size model of a leading feature set up in place—that we must consider it necessary in work of unusual importance to resort to the study of a full size model of the whole, or at any rate of the whole front? One thing is certain—that however much the frequent use of full size models may increase perfection it is pretty sure to decrease power. To do without such aids is a struggle for the imagination, but it is exercise that makes it strong. The strain to conceive a design "in the round," the practice of visualizing it by the help of other buildings that have little in common with it but similar bulk, the consideration of detail by criticizing existing examples, the study of one's own earlier work in the light of new experience—this habit of brooding over a design, engendered by the very uncertainties it involves, is far more educative and developing than the pottering process of altering a model.

CANADIAN PAVILION AT LIEGE, BELGIUM.

When Hon. Sydney Fisher returns to the Capitol he will decide upon the purchase of a site for the Canadian pavilion which is to be erected at Liege Exposition. Liege is a great centre in Belgium and any display which Canada makes there will be brought prominently before a large consuming population. The cost of Canadian building, including the site, may run to $45,000.

FOR THIRTY DWELLINGS.

The section of land purchased recently by Professor Goldwin Smith, on Gerrard street, east of the Don, as sites for attizans' dwellings, will be handed over to the Artizans' Dwelling Company. The land secured will provide sites for thirty dwellings.

PRACTICAL LESSONS FROM THE BALTIMORE FIRE

At last we have got a report upon the Baltimore fire which is of undoubted value, coming from a disinterested and authoritative source, the British Fire Preventive Committee. This body is publishing a quarterly journal* of which Number 1. is occupied entirely by the special subject of the Baltimore fire. This utterance, which is called a Record of the Baltimore Conflagration is the work of Mr. Edwin O. Sachs, who is the chairman of the five Prevention Committee. It is a compilation from American documents and a summary of his own opinions. The remarkable thing is that out of the enormous crop of published utterances, supplemented apparently by a flood of information, opinions and theories from correspondents in the United States, he has been able to select only three reports that he considered honest. These are :—1. The report of Capt. Sewel, of the Corps of Military Engineers at Washington, which may be called the official report of the U. S. A. Government upon the catastrophe. 2. The Report of the Boston Mutual Experiment Station, called the Insurance Engineering Experiment Station, which is under the direction of Mr. Edward Atkinson, the first mover in the Field of Fire Prevention. The report is by Professor Charles Norton who is in charge of the Station and is approved by Mr. Jos. P. Gray, consulting Engineer. 3. The Report of a Special Committee of the National Fire Protection Association of the United States. Of the rest, some reports are said to be the wilfully distorted accounts of local officials on their defence, of local architects and contractors interested in the various buildings affected, of purveyors of fire-resisting materials desirous of proving the value of their wares, of Commissions and Commissioners with a specific purpose and that in the interest of some party or parties financially concerned in the fire, such as, for instance commissions of the Insurance Companies who had to keep an eye on the reduction of claims made against them and were inclined to take an optimistic view of damage done. Even experts of high standing Mr. Sachs finds are turned into special pleaders by "those far-reaching financial influences that appear to dominate every thing American." "The extraordinary power" he says "of certain sections of the so-called "fire-proofing' trade of America is an extraordinary factor that has to be considered when dealing with the Baltimore fire, for that specialist trade stands in very close relation to the great contracting companies, and these again are in close business relationship with the great financial corporations, insurance, and other institutions that have money to place in real estate, and may thus be said to be directly or indirectly in touch with parties with whom relations would seem very unlikely in this country."

These comments on the nature of most of the conflagration literature explain the smallness of the portion of it that Mr. Sachs has taken for his record. They are also worth noting for the consideration of readers of fireproofing literature in general.

The reports included in the record and Mr. Sach's summary, deduced from his whole studies of the subject, come to conclusions so much in agreement and mutually supplementary that it will be useful to bring these conclusions together under subject heads, first to consider the evidence given of the behaviour of different building materials in the fire, and secondly, to consider more generally how the planning and construction of buildings can be made to contribute to their safety if attacked by fire.

MATERIALS.

Hollow Terra Cotta Tile.—As a protective covering this has proved unsatisfactory in every situation. The principal trouble is that it breaks. It breaks in a heat less than that in which it was baked originally so that this cannot be due to chemical change in the material. The explanation given is the difference of expansion between the part exposed to the fire, (which is constantly called the web in these reports) and that which runs in at right angles to the field of exposure and has one side adjacent to the dead air within the block. The consequence is a rupture at the junction, and the outer web, (the protecting flange) drops off. In the case of column coverings and partitions, the resulting instability appears to be sufficient to destroy the further usefulness of the protective covering and complete its ruin. Good work and good mortar in the first place would greatly increase the stability of this material and its value as a protection. The reports lay emphasis upon the extent of the losses in the Baltimore fire which are really due to bad workmanship.

The cure suggested is greater thickness of the "web". It it is not the material which is at fault so much as its form. The web is now rarely more than 5/8 in. thick and soon gets red hot. Prof. Norton questions "whether any floor, containing so little material on its outer faces as did these hollow blocks, could remain sufficiently cool in this fire to avoid serious injury by expansion." Capt. Sewell suggests that the web should have a minimum thickness of 1½ in. (Mr. Sachs says 2 in.) "So that the entire variation in the temperature would occur within the thickness of the exposed web." Then he thinks "if made porous and "of good clay "the material "would probably he about equal to brickwork."

In the case of floor construction of this material Prof Norton thinks the rupture of the protecting flange is hastened by the constructive form—a segmental arch, expanding on its lower surface and crushing the members of that surface. The National Fire Protection Association give another reason for preferring flat arches to segmental; viz. that the lower face is further removed from the strain-curve of the arch, and the breaking of the lower face will not impair the strength of the arch, as it would if the arch were segmental.

All coverings for the lower flanges of beams and girders appear to have failed under intense heat; flange tiles held by the skew-backs of tile arches broke, as did shoe tiles for girders; sheet metal clips failed; tile which was only held in position by mortar dropped off. In some instances the failure of the shoe-tile also permitted the tile protection to the web plates of the girders to fall off.

The National Fire Protection Association adds to the floor question the following "conclusions" :—"The space between the floor and the floor arch should be filled with concrete of a good quality. It is important common cinders without any cement should not be used for this purpose. It has been found that, due to lack of a hard permanent filling for this space, large safes have fallen a distance of about six inches before striking the arch. This gives them some momentum, which adds to the shock which the arch is called upon to sustain."

Brickwork.—For an efficient fire resisting and protective material it is agreed there is nothing like well burned ordinary brick of good quality not vitrified, and well laid—in cement mortar for perfection. This Capt. Sewell says, will stand the application of both fire and water many times without damage to itself.

The 4 in. brick protection used on exterior columns and also on interior columns was without exception practically intact and as firm as before the fire. This coincides with the experience in former fires. Brickwork combines rigid construction and the necessary fire-resistive qualities.

As an external facing, where the question of appearance is involved, brickwork is not free from chipping; but it is in pressed brick facing that this was most noticeable. As a preventive of spalling, Capt. Sewell recommends round corners.

Prof. Norton found no fault with red bricks but says "where brickwork of a lighter colour, ornamented with terra cotta, was used, considerably more damage was noticeable, especially after the slight snow storms of the week following the fire."

*Journal of the British Fire Prevention Committee, 1 Waterloo Place, London, S. W. Single numbers 5 shillings. Annual subscription for the four numbers of the journal and occasional supplements 16 shillings (post free).

It is essential that brick facings should be properly bonded to the wall with headers. Metal ties and corner brick bonding (American bond) were proved inefficient. Capt. Sewell says "face bricks laid up without other bond than metal ties were stripped bodily from the wall in large areas. This is a new and strong argument against a very prevalent pernicious practice, and it is to be hoped it will be the beginning of the end."

ARCHITECTURAL TERRA COTTA.—Captain Sewell says, "there are records enough of hollow terra-cotta failing under expansion strains when heated. Still, it was thought that architectural terra-cotta was reasonably fire proof when used in external walls. Its behavior in Baltimore is a distinct disappointment, for it can no longer be classed as a fire proof materal." It suffered worse than stone, for while all building stones spalled and chipped "the terra-cotta cracked and fell to pieces, and in some cases its color was changed and the heat seemed to have destroyed its texture so as to render the material soft and friable," and "highly ornamental terra-cotta suffered notably worse than that which was relatively plain." He suggested that "in the case of ornamental terra-cotta, it is possible that filling all the cavities with concrete might improve its fire-resisting qualities by preventing the exposed parts getting so hot as they do when backed by a dead air space, yet I saw some pieces of the Maryland Trust Building which had been filled with mortar, but which failed nevertheless."

STONE.—No building stone can be used for protection against fire. It is unsuitable from this point of view, both for construction and finish.

The exterior stone facing of walls was usually badly broken. Marble and granite are especially susceptible to damage. Interior marble finish was practically all destroyed. Marble not only spalls like granite, though not so badly, but calcines under long continued heat. Capt. Sewell found that stone with projecting parts of any kind suffered more than similar stones entirely flush with the wall. The reason is similar to that which causes the damage to terra-cotta; the projection of parts exposes a relatively small mass of the stone to sudden changes in temperature, while the body of the same stone remains relatively cool. This is true not only of mouldings and other ornament which projects beyond the ashlar face, but of variations in the ashlar face itself; it is the spalled face of the Custom House which furnished him with the text of this part of his discourse, as he found this damage "aggravated by the fact that most of the ashlar was cut with raised panels in the centre."

PLASTER.—The National Fire Protection Association makes the conclusion that "plaster blocks and plaster on metal lath are unsatisfactory for use as a fire-protective covering for columns or other structural metal work."

Plaster blocks, used to protect the columns in the Equitable Building, crumbled away from the columns and fell on the floor.

Plaster on metal lath had been previously found to be unreliable. It is especially susceptible to damage by hose streams. In this fire, Capt. Sewell says, "metal lath and plaster failed everywhere." Yet, though plaster is not sufficient in itself for a fireproof covering it is not without value in a fire. "Applied to other fireproof coverings," Capt. Sewell says, "it will in itself resist fire a long time and thus lessen the severity of the test for the material behind it."

CONCRETE.—All the reports speak well of concrete, though it does not appear in the conclusions of the National Fire Protection Association. Mr. Sachis wants concrete or composite metal and concrete floors in all business premises of the shop, warehouse, and factory class. He will admit terra-cotta for iron protection if nowhere thinner than two inches, and brick for partitions, but mentions concrete first.

Capt. Sewell's opinion is—"Concrete undergoes more or less molecular change in fire; subject to some spalling. Molecular change very slow. Calcined material does not spall off badly except at exposed square corners. Efficiency, on the whole, is high. Preferable to commercial hollow tiles for both floor arches or slabs, and column and girder coverings. In form of reinforced concrete columns, beams, girders, and floor slabs, at least as desirable as steelwork protected with the best commercial hollow tiles. Stone concrete spalls worse than any other kind, because the pieces of stone contain air and moisture cavities, and the contents of these rupture the stone when hot. Gravel is stone that has had most of these cavities eliminated by splitting through them during loug ages of exposure to the weather. It is therefore better for fire-resisting concrete than stone. Broken bricks, broken slag, ashes and clinker all make good fire-resisting concrete. Cinders containing much partly-burned coal are unsafe, because these particles actually burn out and weaken the concrete. Locomotive cinders kill the cement, besides being combustible. On the whole, cinder concrete is safe only when subject to the most rigid and intelligent supervision; when made properly, of proper materials, however, it is doubtful whether even brickwork is much superior to it in fire-resisting qualities, and nothing is superior to it in lightness, other things being equal."

One building in the Baltimore fire, No. 111 E. German Street, which was constructed throughout—columns, beams and floor arches—of reinforced concrete on the Hennebique system, had a severe test, as it was surrounded by non-fireproof buildings. Capt. Sewell reports of this building that in the lower storeys the concrete was absolutely unimpaired, though the contents of the building were all burned out. In the upper storeys where the heat was intense, (Prof. Norton found evidences of temperatures up to the softening point of iron) the concrete was calcined to a depth of ¼ to ¾ in., but it showed no tendency to spall except at exposed corners. The exposed corners of columns and girders were cracked and spalled, showing a tendency to round off to a curve of about 3 in. radius. Capt. Sewell takes from this a hint to round such corners to a radius of 3 in. in the first place, as a preventive of cracking and spalling, saying it would "add much to the resistance" not only of concrete, but "of all materials used in masonry, whether bricks, stone, concrete or terra-cotta—if they are exposed to fire." On wide flat surfaces the calcined material—which was here at the minimum of ¼ inch.—showed no tendency to come off, and Prof. Norton finds in this an additional protection against fire. He says:—"When brick or terra-cotta are heated no chemical action occurs, but when concrete is carried up to about 1000 degrees Fahrenheit its surface becomes decomposed, dehydration occurs and water is driven off. This process takes a relatively great amount of heat. It would take about as much heat to drive the water out of this outer quarter-inch of the concrete partition as it would to raise that quarter-inch to 1000 degrees Fahrenheit. Now a second action begins. After dehydration the concrete is much improved as a non-conductor, and yet through this layer of non-conducting material must pass all the heat to dehydrate and raise the temperature of the layers below, a process which cannot proceed with great speed."

Prof. Norton could find little difference in the action of the fire on stone concrete and on cinder concrete. He considers that the burning of bits of coal in poor cinder concrete is often balanced by the splitting of the stones in the stone concrete. He notes, however, that, owing to its density, stone concrete takes longer to heat through.

(A second article upon this subject will deal with lessons relating to planning and construction.)

A French architect, M. Pénin, who has recently been building on the site of the Hotel Mascani of Paris, an old mansion dated 1678, has nothing good to say of its construction. The floors, he says, sank by their own weight. In general, there was little where there ought to be much, and much where there ought to be little. To this decline, from the perfection of French construction in the Gothic centuries, some clue is given by M. Pénin's account of a flue which was carried of small—and presumably of reduced—girth through the middle of the floor beams. An architectural conception thrust upon the plan instead of proceeding from it falsified construction all through.

OUR ILLUSTRATIONS.

HOUSE IN NEW HAMPSHIRE.

The walls of this house are apparently of brick plastered white. The window shutters are not distinguished in colour, the sash bars carry the same colour across the openings and the roof is either silvered or stained with a silver gray. It is a strong case of simplicity and illustrates its power. There is however a scheme of decoration by climbing plants which owes its value partly to the simplicity of the background and partly to the extension of the trellis over the whole front, in lines which run with the horizontal lines of the openings and are in scale with the building. The nature of the trellis work is seen in the view of the doorway below. Its effect at a little distance, as seen in the general view is much more architectonic than the small diagonal lattice which we are accustomed to see. It adds to the character of the wall; and indeed the inventive designer may see in its apparent unity with the

DOORWAY OF HOUSE IN NEW HAMPSHIRE.

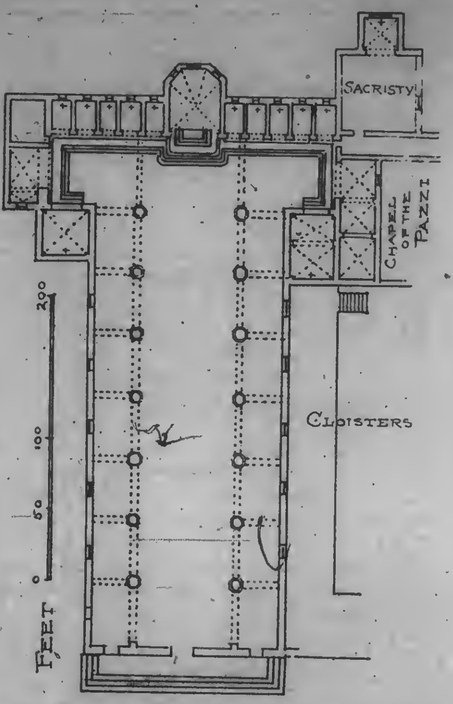
wall a suggestion for enriching the surface of a concrete wall by fillets formed in the course of its erection.

THE CHURCH OF SANTA CROCE, FLORENCE.

The Franciscans, for whom Santa Croce was built by Arnolfo di Lapo, were a preaching order and a poor one. They wanted a big plain church for little money; so that we have in Santa Croce an example of the thirteenth century treatment of a cheap job.

With the exception of the east end, it is as simple as a barn, but is nevertheless the most impressive church in Florence. Size has something to do with it but also the constructional vigour of its design. The nave arcade and aisle arches are 65 feet to the apex, and the plate of the main roof cannot be less than 90 feet above the floor. It is this great roof of king post trusses that is so impressive, partly from its height and partly from the frequency of the principals—about 12 feet on centres. This, in a perspective of 350 feet gives an apparent closeness, which produces a beam effect upon a magnificent scale.

The apse of the east end does not occupy the width of the nave. Its relation is, as suits the T shaped



cross of the plan, rather with the ten chapels, two of which appear with it in the view up the nave shown on on the illustration sheet. It will be noticed that the windows on either side of the apse are not in the same plane; the lower range being at the back of the chapels.

The aisles are roofed by a series of gables pitched from the backs of the aisle arches, which have, therefore, each a valley above. The timbering of these roofs shows within. This arrangement (which even in Italy must require some attention) was made for the sake of strength, and gives, much more than a sloping roof, an appearance of stability to the exterior.

HOUSE ON ROXBOROUGH STREET, TORONTO. — MESSRS. SPROATT AND ROLPH, ARCHITECTS.

The drawings on the illustration sheets are reduced to a scale of 8 feet to an inch. The house faces south. The main construction is simple and rectangular, but the plan is interesting from a variety of effect, due to recessing the windows on the south side, and to a difference of level between the drawing room and the living room, which appears again in the hall in the way of a pair of landings to reach the same level, for access from the hall to the dining room and to the kitchen department, which is, for the purpose of service, on the same level as the dining room. The first characteristic of the plan is, however, spaciousness, without which the variations in level would fail in effect and the recessed windows cease to have their present contrast with plain wall surface. The hall and living room placed end on to one another give the

house as much extension as possible on the south. The smaller size and different disposition of the drawing room make a change which relieves the interior—and also the front—from monotony. The dining room and kitchen arrangement is naturally made as compact as possible. The kitchen is all the better for retreating from the sun behind the front part of the house. In the case of the dining room this retirement is a concession to shade on the verandah; but the dining room is in close and open connection with the living room, where there will be plenty of sun. It is interesting to see a return to the old fashioned vestibule, with external doors which, when not in use, fold back as panelled sides to the recess. The projection of the vestibule into the hall is made to tell on the inside as a pair of recessed windows on the long side of the hall.

REVIEW

We have received a handbook for architects, on Locks and Hardware,* by Henry R. Towne, (President of the Yale & Towne Manufacturing Co.), which contains definite information, such as an architect wants, about locks and other interior fittings, usually called "Builders Hardware" in the United States. It is a general treatise with special illustrations, drawn for the most part from the products of the works under the management of the author. This though a distinct lead in the direction of Yale has less of the nature of a justification of the goods than of that direction to their use and guidance in using them with which we are familiar in the handbooks of the manufacturers of steel beams. The Yale productions are well known and anyone who chooses to take suggestions from this handbook will do so from choice, knowing beforehand the standard of quality and looking only for information as to what will suit his requirements. The information he will find is as follows, divided into ten Parts:—

Part I. History, the development of lock making and "Art Metal Working" in America; chiefly a reprint of articles published at different times; one by Montgomery Schuyler on Artistic Hardware.

Part II. The Mechanics of Hardware. A valuable section, explaining, by the help of illustrations, the construction and mechanical characteristics of locks and other articles. A knowledge of this is essential for a proper selection and application of hardware finish.

Part III. Art Metal Work & Ornament. This consists chiefly of historical studies of all the Schools of Ornament (thirty four of them, beginning with the Cave Dwellers and ending with the Colonial School), by W. W. Kent. There are a great many illustrations showing characteristic examples of the Schools and, when the Yale & Towne Co. have produced hardware in one of these styles, illustrations are appended, with page numbers for their identification in the classified lists given later in the volume. This part concludes with a section on metals and their finishes and one on the obscure subject of the momenclature of the finishes.

Parts IV. to VIII. give Classified Lists of Yale hardware; Locks and Latches, Locks in Sets, Plain Hardware, Hardware Groups and Cabinet Hardware. All articles illustrated from photographs, all priced on a system which gives the relative value of different sets, materials, finishes, etc., and their absolute value near enough for the purpose of a preliminary estimate.

Part IX. Specifications and Forms of Contract.

Part X. Miscellaneous Information; among other things a useful hint about drawing for hardware and some illustrations of different types of casement window construction. There is a glossory of terms, at the beginning of the book, with the motto at the top—"Accuracy in Language promotes Accuracy in Business." The promotion of accuracy is the purpose of the book and constitutes its value.

*Locks and Builders' Hardware, by Henry R. Towne. Profusely illustrated. John Wiley & Sons, 43 to 45 E. Nineteenth Street, New York. $3.00.

CORRESPONDENCE

QUEBEC, December 3, 1904.

Editor CANADIAN ARCHITECT & BUILDER:

Sir,—Among the usual number of pertinent articles in your last issue, I find "Suggestions from New Zealand as to escape from theatres in case of fire or panic."

The suggestions are all excellent; but would prove to be useless after a very short season of probation, as no theatre lessee could ever be made to carry them out on account of the curtailing of his profits by as much as it would cost nightly and yearly to pay men to attend to so many entrances and exits and especially in a climate like this, where, if emergency issues were provided with doors opening outward on to iron landings and stairs the same would have to be attended to night and day after every fall of snow or because of ice and sleet offering an obstacle to the outward opening of the doors.

We have had a terrible example of this in the case of the Paris Charity Bazaar, where, though seven emergency doors had been provided, and were at hand to do the needful; the wealthy promoters of the bazaar would not incur the expense of as many men as doors, with instructions not to leave their posts on any pretence and to throw open the doors immediately on the very or mere suspicion of a fire or panic of any kind.

Had this been done, not a single life would have been lost, though of course the inmates would have been the worse of a singed head and burnt shoulders from the burning and falling draperies from above, but all of which would have been restored, hair regrown, scars have disappeared within a few months after the occurrence.

The most instructive lesson in the way of escape from danger in the case of the burning of a theatre, was admittedly that of the latest Chicago horror, where during the conflagration of a new theatre, more than 700 persons lost their lives.

The commissioners named to report on the cause of the catastrophe, arrived at the conclusions which, had they been arrived at and carried out before the fire occurred, would likely have reduced the fire to one without loss of life and have saved half the edifice, the auditorium side, from destruction.

In this case there was on the auditorium side of the building a large ventilator or opening extending from the auditorium ceiling to and through the roof of the building. This, as its name implies, was for the purpose of ventilation—while over the stage end of the theatre there was no ventilator or opening of any kind. Now, say the commissioners, it is especially on the stage side of the edifice that such an opening should have been provided, extending from the stage ceiling to and through the roof.

The tendency of heated air and gases is, as must be well known, to rise vertically and seek an issue into the atmosphere. The hot air and smoke would thus have no tendency to rush, as it did, towards and into the auditorium through the proscenium arch to gain an exit by the auditorium ventilator.

The proscenium was provided with a fire-proof curtain or screen of asbestos. This curtain was not a rolling one; but slid or moved up and down bodily, its ends being armed with slides which were confined by vertical guides for the purpose.

An attempt was of course made to lower this curtain or screen down to the stage floor, which would have effectually cut off the flames from reaching the auditorium side of the building; but all attempts were unavailable to move the screen further down than to within fourteen feet of the floor of the stage; due to the pressure which the current of heated gases from the stage end, where the fire occurred (and always does occur), pressing the curtain slides so tightly against the outer side or auditorium side of the guides, that no force would move it beyond the point it had reached.

The smoke and hot air therefore having no issue from above the stage, continued to pour through the proscenium arch into the auditorium side of the building where it is probable and consoling to think that the audience were asphyxiated before the flames had time to reach them.

The commissioners insist that had there been over the stage end of the building a proper exit for the heated gases, they would have risen vertically to egress through the same without any tendency to invade the auditorium to seek an exit on that side of the procenium wall or wall of separation between the stage and auditory.

This then, of all the possible solutions of probable escape with one's life from a theatre where the stage is on fire (and there is not the least tendency of the fire starting on the anditorium side of the curtain) the true and only one—independently of all other facilities of exit as recommended by the New Zealand architect—is the existence, above the stage, of such an opening as would allow of the smoke and gases passing out direct into the atmosphere, without any tendency whatever to take any other direction.

Of course the opening in the roof, and especially in such a climate as Canada, must be closed to keep the cold out and prevent loss of heat; but this could easily be managed by topping it with a ridge roof of such an acute angle (say 60° at apex) as to cause snow to fall off it, and the opposite flaps or shutters of which would be worked from the stage floor level of the building by wire ropes or even by hempen ones passing down along the walls through iron conductor tubes to prevent the possibility of the ropes themselves being burned by the burning scenery.

In 1854, when the writer designed the Quebec theatre "Academy of Music," asbestos was, so to say, unknown, and there was to have been a solid screen of iron, for raising which bodily there had been provided sufficient height in the rooting above the stage.

This screen or curtain, to disguise or dissimulate it, was to have been covered with mirror in vertical strips of say 3 to 5 ft. in width held in position by silvered sash base riveted to the body of the screen.

Such a curtain reflecting, when down, the whole audience, would have had a fine effect, and at any rate, of whatever nature, such a cut-fire screen should be at hand in all theatres and a cut-fire wall extending from the very foundations to above roof of building, with no other opening than the proscenium arch, or iron doors to other openings through it, if indispensible.

In conclusion, as any additional precaution can never be "*de trop*" and on this head, it may be remarked that in rebuilding the theatre at Antwerp, Belgium, destroyed by fire some 10 or more years ago, a recommendation made by the writer in a paper of his read before the Society of Architects of Canada in 1888, was carried out, and each of the five tiers of surrounding galleries above dress circle level was provided with exterior iron balconies and some 25 doors or exits, 125 in all, leading thereto with outer iron stairs from each tier down to ground level; this allowing of emptying the building of its inmates in less than half a minute of time; while, of couse, the stage end of the edifice is also amply provided with issues to the same effect.

CHAS. BAILLARGÉ.

Mr. Baillarge's suggestion strikes at the root of the danger in theatres. The difficulty of a large opening which must be kept closed and yet must be thrown open in an instant is no doubt as susceptible of solution by automatic action as is the operation of the ordinary fire door. No matter how heavy the doors of the opening may be, if they are hung on pivots it is but a little weight that would make the difference between the balance that keeps them shut and the balance that throws them open.—ED. CANADIAN ARCHITECT AND BUILDER.

A QUESTION OF FEES.

An Ontario architect writes as follows:

The writer wishes to obtain a recognised schedule in pamphlet or book form of the fees that architects are entitled to for full and partial services as architects. Also wish to ask what is usually understood by the profession as full professional services. Does it mean constant attendance at the building during construction, if not, how often would any representative of the firm be required to visit the works to comply with the term full professional services to their client, in the absence of any special agreement.....A large portion of the proposed scheme was abandoned. Are the architects entitled to collect the usual proportion of fees for plans, specifications, details, surveys and measurements. Also the obtaining of proposals from contractors for the same. In this locality the custom has been to collect 50% of the full fees customary.

Answer.—In reply to your letter of November 24, asking for information about architects fees and services: The only Ontario tariff is that of the Ontario Association of Architects, which we cannot very well procure for you if you are not a member of the Association, and indeed it would be of no service to you unless you are. The only scale of charges recognizable by a court of law in a case of a disputed fee, where there has been no preliminary agreement, is the scale which has been in use by the architect or the body to which he belongs; the presumption being that there was a tacit acceptance by both parties of what is customary in that neighbourhood or known to be the previous custom of the architect. You have a right therefore to claim for your work what you have been accustomed to charge; or, in case of discontinued work, for that proportion of the fee which you have been accustomed to charge for the proportion of the work done. On this head the schedule of the Ontario Association reads: "For partial service or in case of the abandonment or suspension of the work, the charge for partial service is as follows: Preliminary studies, 1-5 of the full commission. Preliminary studies and general drawings and specifications sufficient for estimate and contract, 1-2 of the full commission. Preliminary studies, general drawings, specifications and details, 4-5 of the full commission. For superintendence alone, 2-5 of the full commission for the work to be superintended." This is generally considered to divide the fee into parts fairly proportionate to the amount of work set off against each part.

As to superintendence there is no way of measuring it except by efficiency. The intention in superintendence is to see that a work is being carried out in conformity with the design, specifications and directions, so that the work is as suitable for its purpose as it was intended to be; and to watch its progress with a view to certifying correctly the payments that are due as the work progresses. The architect, in the absence of a more definite arrangement, is supposed to judge for himself when and how often visits should be made for these purposes, and the only proof of his neglect will be in results.

A QUESTION ABOUT VENTILATION.

A correspondent asks for information as to recent methods of ventilation:

Answer.—A reply to your request for information as to recent methods of ventilation is a matter far beyond the scope of a letter. There can hardly be said to be new methods, only new contrivances for carrying out the one old and only method—the application of power to move the air. Of these contrivances the simplest is heat, and, inasmuch as ventilation is usually required during the winter months, the application of heat is within the compass of everybody building in this country. Ventilation and heating should be studied together as one scheme, calculated in mutual relation; but this requires science, and to that end study, for which purpose an excellent book is Heating and Ventilation by Professor Carpenter of Cornell University. It is published by John Wiley & Sons, New York, and the catalogue price is $4.00.

AN ENGINEERING FAMILY.

The City of Quebec has appointed Mr. W. D. Baillargé to the office of City Engineer; the place his father, Mr. Charles Baillargé, filled, with so much distinction, for 33 years.

The United States Government through the Bureau of Foresty is carrying on some interesting experiments in order to determine the rate at which different kinds of timber will season. Certain kinds of timber, it is known, are improved by being soaked in water for different periods of time, but the chemical or physical changes which occur are not fully understood, with the result that the best economic usage of timber is largely a matter of accident. The enquiry referred to may prove highly valuable in discovering means for the arrest of decay, the best utilization of certain parts of the tree, and so forth.

AFFAIRS IN TORONTO.

THE site of the new building for the Toronto Public Library is not settled. As far as users are concerned, there seems to be good arguments for both down-town and up-town sites; but the balance is in favour of an up-town site for the permanent and valuable part of the library, which will be used by students, and a lending branch in the city. The site chosen is the Perkins estate on College street, where the building will be in close association with the university group and on a thoroughfare which, from this association and from other accidents in its course, has more possibilities for the creation of beauty than is usual in the streets of Toronto. It is impossible, however, from the point of view of advantage to the neighbourhood in which the building is placed, not to regret the loss of an occasion given, if the site adjacent to the City Hall had been found desirable, to make the proposition include the whole block of land between the City Hall and Osgoode Hall. The argument would have been that, if we house valuable books and unique documents in the middle of a great-risk fire district, the building that contains them should be isolated; the result would have been the redemption of that part of Queen Street.

THE air of Toronto is heavy with building projects. The Union station is an actuality. Messrs. Darling & Pearson, E. J. Lennox and A. H. Chapman, (the latter associated, for this purpose, with Messrs. Sproatt & Rolph) are understood to be retained as competitors for the new building, if they are not as yet actually engaged upon it. Its erection will mean the transformation of Front street between Yonge and York streets.

THE EXHIBITION BOARD will soon be applying for a grant from the city. They are talking of new buildings. There was also some mention of a plan of the grounds, but not in the same breath; not at any rate with the same amount of breath. If, however, their request for a grant is to be supported by anything definite, it should include a definite plan of the grounds. The success of the Exhibition appears to be such as to justify the City Council in taking a hand in its extension and improvement, but, though the money given is given for building, the value of the buildings, as a means of making the Fair attractive, depends so much upon their disposition upon the grounds that it is a plan of the grounds that chiefly concerns the custodians of the public purse.

THE UNIVERSITY is about to begin the Convocation Hall, for which plans have been prepared for some time, and the Ontario Government will expend, on a new building for the department of Physics, the $180,000 received from the Grand Trunk Railway as the purchase price for the old Parliament Buildings on Front street. It is understood that the position of this building in relation to the other University buildings has already been considered. If it is anywhere within grouping distance of the main building, it is to be hoped that it will fulfil the obligation—difficult, but possible—of harmony without imitation. The great want in the University set of buildings is of a plain type that will harmonize with the ornate main building. This has been done at Columbia. The scientific buildings are machine shops and the library is a monument, but they harmonize.

A UNIVERSITY RESIDENCE is being talked of. Mr. E. C. Whitney, of Ottawa, has given, to the trustees of the University, $15,000 to be the nucleus of such a residence. A good deal more will have to be got before anything can be done, but the sum ultimately aimed at need not all be got at once. A good suggestion was made, in the newspaper account of the presentation of the gift, that the proposed residence should be a composition of units which could be built separately; the whole when completed enclosing a quadrangle. Each house would hold fifty or sixty men who would be under the general direction of a member of the faculty in charge of the house. University men are, like other men, bnt children of a larger growth, and the growth is not only less large but comes upon them rather suddenly, when they leave the restraints of school for a freedom such as they never had before, nor indeed, it may be said, are likely ever to have again. Personal influence of the right kind is even more important than rule in making the most of the double opportunity—the opportunity for studious seclusion, and, at the same time, for constant association with equal minds—which makes the charm and is the advantage of college residence life. And this influence is most effective where the field is not too large. Houses for 50 or 60 making the sides of a common central space, quadrangular or otherwise, would make an excellent system of formation for a residence or a series of residences at the University. It can be built, a unit at a time, as funds come in. If the University had succeeded in selling its land to the north of Hoskin avenue it might now have the funds for such a residence but it would not have the land. Now, in consequence of that fortunate failure, it has the land and, as the province is on the bound, there may be, now or soon, other people who have the funds.

THE HOUSING QUESTION has, with the approach of winter, become more acutely felt to be a serious matter. Inconvenience is felt by all classes, but the poor are suffering. It is an expensive matter for a whole family to board. Poor people must have a domicile of some kind, and the shifts they have been put to are sometimes startling. Homes are made in stables, sheds, old street cars, tar-paper shacks, etc.; all duly visited by a local reporter with the freedom of a friend of the family; and the willingness shown, by those he visited, to talk about their affairs is a symptom of the strain they are feeling. The occasion has roused Mr. Goldwin Smith to try to organize a joint-stock company to build workmen's houses and rent them on the basis of a fair profit for the capital invested. This is a large-minded and truly philanthropic scheme. To apply money where the public good requires it, and, while asking for a fair profit, to ask for nothing more, is a conception of the use of capital, which, if it obtained generally, would bring about happiness on the earth without failure and without delay. It is to be hoped that this scheme will work without failure, and also—as the need for it is pressing—without delay.

MONTREAL.

THE YEARS CHANGES IN THE CITY.

Of city buildings which are likely permanently to enhance or detract from the beauty of the town, the greatest number during the past year has been erected in St. James street. There the banks congregate and it is these institutions which have easily held the lead in building operations not only by the number and extent but also by the costly and substantial character of their enterprises. As a rule too they have set excellent examples in erecting buildings of good fireproof character—the system of cased steel work with flat terra cotta arching for the floors being adhered to in almost every instance.

The 'armed cement' construction usually adopted for the roof of this class of buildings suggests the favorite French method of fireproofing; but though now being advertised here we do not know of any examples where a "beton armé" system has been thoroughly applied in Canada. Apart from banks, we still see too many commercial buildings being built with little or no attempt at fireproofing. That this should be done by private firms is not, perhaps, very suprising, but it is wholly so to find the new wing of the law courts setting the example of wooden joisted floors at this time of day.

We have formerly spoken at some length about the head office of the Bank of Montreal—easily the first in architectural merit of all the buildings in the city. The works which have been in progress there are now nearing completion and the 87th annual meeting of the bank was held in its new chambers on the 5th December.

Of the other banks in St. James Street, the Bank of Ottawa building nearly completed and that of the Sovereign Bank, now hastening to get its steel skeleton clothed in more comfortable materials, both have soared to the full height permissible by the city bye-laws. Both belong to a type of design derived from the high buildings of American cities. That is to say, they endeavor to present a building of extremely high narrow proportion and to preserve unity of effect by strongly emphasing a storey or two at the bottom to provide an architectural base, again strongly modelling the top as a crowning member, leaving the intermediate storeys plain as a contrasting body. These are from the designs of Mr. H. C. Stone.

On the opposite side of the street the Metropolitan Bank designed by Messrs. Finley & Spence shows on a smaller scale a similar general treatment and it is here very palpable that the smaller bulk bringing the whole building more within the compass of the eye is more suited to carry a scale of detail which can be refined without losing strength and interest.

For the Imperial Bank, the large building at the south end of Victoria Square, which was gutted by fire a couple of years ago, has been remodelled under the direction of Mr. A. T. Taylor, whose departure for England makes an important change in the ranks of the Architects of Montreal.

The Royal Bank of Canada's new building in St. Catharine Street and also the small branch of the Bank of Montreal in Greene Avenue close by were referred to last month. Farther east in St. Catharine Street, Mr. A. H. Lapierre has erected a three storey building of Quebec limestone for the City and District Savings Bank, the exterior of which is now completed.

Outside of St. James Street, the "down town" streets present few important changes. A new building is now being erected at the corner of Notre Dame Street and Cote St. Lambert—the result of expropriation changes. The principal improvement in Craig Street has been the recent thinning of the forest of telegraph poles, which helps to make that locality so picturesque. Some of the finest giants have lately been felled in pursuance, we understand, of the intention to have the wires generally placed underground.

As regards stores nothing of first-class importance has been carried out during 1904. Perhaps the greatest number of new works of this class is in St. Catharine Street. W. H. Scroggie Limited have completed the structural work of an addition to their store which, if not rising to architectual magnificence, at least completes the block from street to street in a uniform and tidy manner. The Renouf building, almost opposite, was completed early in the year, and in Union Avenue, not many yards away, a new store built and elaborately finished for a fashionable tailor exhibits much careful ingenuity of design.

In some of these buildings one may observe a rather plensant introduction of delicately modelled broad metal frames around the store windows. If this treatment does not compensate for the architectural defect inherent in the slenderness of support that shopkeepers demand, it has, at any rate, the merit of giving interest and emphasizing the metallic nature of the supports.

In St. Denis street, not far from the corner of St. Catherine street, the Polytechnic School has recently been completed. This excellent building, from the office of Mr. E. Vanier, is one that has an agreeable air of appropriateness to its purpose. Designed without undue ambition its well understood and wholesome detail raises it well above the commonplace.

The building for the McGill Young Men's Christian Association in Sherbrooke street has now almost attained its full height and the Montreal Amateur Athletic Association premises in Peel street, referred to in a previous issue, are being completed internally. At a similar stage, or rather less advanced, is the new Maternity hospital at the corner of St. Urbain and Prince Arthur streets.

Of dwellings large numbers have been built during the year, mostly of a humble class in the poorer outskirts. A striking feature in the better localities is the number of apartment houses which have appeared; some of them new, but many the result of a transformation of private dwellings which have been swelled out in all their dimensions to contain as many apartments as possible. In these it need hardly be said the money making purpose is more obvious than the architectural excellence. They are, however, eloquent witnesses to a particular feature in the life of the citizens. Montreal becomes more and more markedly a city where one half of the population makes its living by keeping house for the other half, and the people with a private home life of their own are becoming a smaller and smaller proportion of the whole.

For next season's operations they are now getting in the foundations for a large hardware store in Bleury street, near Craig street, Mr. H. C. Stone being the architect, and a new seven-storey fireproof store is advertised as about to take the place of some of the older buildings on the south side of St. Catherine street, a little west of Peel street. The McGill Students' Union building and the new club house of the Mount Royal Club, both in Sherbrooke street, give signs of being prepared to spring up with the coming of spring. Next year should also see substantial progress made with the new Notre Dame hospital and the Fever hospital at Point St. Charles. The erection of the latter has been delayed, we understand, owing to certain preliminary financial difficulties.

CONCORDIA SALUS.

THE NEW PEACE PALACE AT THE HAGUE.

Every one who has visited Brussels, the beautiful capital of Belgium, will remember the splendid pile of the Palace of Justice which forms such a striking feature in the modern architecture of that city. That building has been decided upon as the model for the new Peace Palace at The Hague, which is to be erected through the gift of Mr. Andrew Carnegie, and which, on a smaller scale, will be exactly similar to it. The new palace will cost $1,640,000, and will be a superbly beautiful building. The main audience-room, where the sessions of the Court of Arbitration will be held, will be 270 feet long by 120 feet wide, and will cover no less than 12,000 square feet in area. In addition, there will be a committee room, and on the second floor two spacious rooms, one for the president and the other for the secretary of the permanent Court of Arbitration. The dome surmounting the palace will be supported by two galleries, the lower square shaped, the upper, round, flanked by great bronze statues of Clemency, Justice, Law and Strength.

A PLUMBING EXHIBIT.

PROVINCIAL BOARD OF HEALTH PLANS UNIQUE DEMONSTRATION

The Provincial Board of Health is providing space for an exhibition of specimens of plumbing work and fixtures, ancient and modern, to demonstrate in a practical way the great advance which has been made in the manufacture and installation of the same. Mr. M. J. Quinn, for twenty years mechanical superintendent of the Public Works Department, is making the collection for the board. The specimens will not only be exhibited, but lectures and practical talks will be given to all interested, with a view to implanting and cultivating a correct idea of the intimate relations between proper hygienic conditions and sanitary plumbing.

TWO PAPERS ON REINFORCED CONCRETE CONSTRUCTION.

These papers were read at a regular meeting of the Royal Institute of British Architects on November 21 last.

The first paper, by Mr. William Dunn was as follows:—

CONSTRUCTION AND STRENGTH OF REINFORCED CONCRETE.

Owing to many unpleasant experiences, there was, he remarked, a feeling among many architects and builders that concrete was a treacherous and unreliable material. In all such experiences there was something mysterious; the cement came from a maker of established repute, it had been specified "Best London" Portland cement, the sand and gravel looked clean, and the builder was an honest man. Nevertheless, it failed to set, it cracked, it thrust out the walls, and generally led to a great deal of trouble. To make good concrete much care in the selection of the materials and in the mixing was required. The cement was the most important ingredient, and the only way to get good cement was to constantly test it and reject that which was faulty. If the fact that it is frequently tested becomes known to the merchants, it will be found that bad cement would be less and less frequently sent. When floors, walls, roofs, or pillars are made of concrete, a bad cement is really dangerous to life. It would be an excellent plan if the Institute, the Builders' Institute, and the cement makers could agree upon a standard suitable for architectural work. But until such a standard was fixed, architects must describe it themselves in their specification. Many cement experts had given model specifications, but there are some points in cement specification required for building work which a cement expert scarcely values.

FINENESS OF GRINDING

Is all important, as only the very fine particles have cementitious value. Foreign makers were much ahead of us a year or two ago; now we can get an English cement which will all pass a 76 by 76 and leave only 18 per cent. on a 180 by 180 sieve. This is a very fine cement, and perhaps too good for ordinary cement. All, however, should pass 50 by 50 and leave only 5 per cent. on a 120 by 120 sieve. A good cement is economical; we make a stronger mortar or concrete with much less of it, so that the extra cost is more than repaid. The particles which are retained on a 50 by 50 sieve are practically so much sand. The auther strongly urged the use of a slow-setting cement. Pats made with the minimum quantity of water should set in not less than five hours when the temperature is at 34° Fahr., and in not less than twenty minutes when the temperature is at 75°, and proportionately in time when the temperature is between these points.

SIMPLE TESTS.

Soundness or constancy of volume is one of the most important qualities a cement should have. Tests without elaborate apparatus are fortunately available. Make two cement pats on small pieces of glass, tap them out to a circular shape, about 3in. diameter, ¼in. thick in the centre, and with thin edges; keep one under water and one in air for several days. The cement should then show no cracks, change of shape, or tendency to curl off the glass, if sound. The author described other methods of testing, and strongly urged architects to test their cements by one and all of them as often as they could; it would save many after troubles. Tensile strength he regarded as the least important; it is the test on which the most varied results may be got by different observers according to the method employed in filling the briquettes. A strength of 400lb. per square inch at seven days, and 25 per cent. increase in twenty-eight days, is usually asked for and easily attained; many briquettes he had found go up to nearly 1,000lb. at seven days.

FREE LIME IN CEMENT.

It is not unusual to specify that sufficient cement should be delivered on the works at starting, kept stored in a dry weather-proof shed to a depth of not more than 2ft., and turned over daily for a fortnight before use. It is found that makers send out the cement hot from the mills, and (unless it is very high-class cement) it is much improved by air slaking. Aëration seems to improve an inferior cement by the slaking of the free lime, which if it took place in the work would be dangerous. A thoroughly sound cement should have no free lime in it, and is not improved by air slaking; it rather suffers. Cement in which there is no free lime can be produced by the maker, but it requires much care in the making, and is consequently expensive. As regards the

AGGREGATE,

the strongest concrete is made with gravel; the size should vary from large sand to small stones, passing a ¼in. or ½in. mesh, for floors or walls, to 1½in. or even more for foundations. The cleanness of the aggregate and the water is most important, as is also the cleanness and sharpness of the sand. Small sand, such as would run in an hour-glass, is utterly useless—the sand must be fairly large and sharp; it should vary in size: the more uneven the sizes the smaller the voids. The finer the sand the less the strength. There should never be more than three of sand to one of cement.

MIXING THE MATERIAL.

The author described the process of mixing concrete, which should always be done under supervision. Concrete mixing machines are much used in America and on the Continent, producing very good and uniform results. These machines are rarely seen here. One has frequently seen on a building a lot of concrete mixed up, and left for an hour or so before being set in place. If too stiff more water was added. Such treatment of the material invites disaster; initial set begins very quickly, and the concrete should be put in position as soon as mixed, and without a moment's delay. When the concrete is eventually laid on the centring, or put in the moulds, it is put in in thin layers 2in. to 3in. thick, and beaten down with iron beaters very carefully all over. This is essential in order to prevent the formation of voids, and to increase the resistance of the concrete.

STRENGTH OF CONCRETE IN PLACE.

Mr. Dunn then treated in considerable detail of the strength of the material in place, describing various tests of cement made by eminent scientists, and illustrating by diagrams and mathematical calculations. For further mathematical investigation of the subject, he referred those interested to Professor Perry's "Applied Mechanics" (p. 345), and to M. Considère's experiments, the results of which were communicated to the French Académie des Sciences in a note of March 18 last—an abstract of his communication appears in the *Genie Civil* for April 30. These writers base their discussion on "Rankine's Ellipse" of Stress, which, as given in Rankine's own words, is not easy to grasp. In Alexander and Thompson's "Elementary Applied Mechanics," however, the ellipse of stress is fully explained, and a preliminary reading of part of the last-named book should enable anyone to follow Considère's or Perry's reasoning. The resistance to the swelling and bursting action to which columns in concrete alone would be subject can be produced by binding the columns with iron or steel wire. Makers of concrete columns do so bind these according as the effect to be combated is more or less clearly understood. What is done in the Hennebique column is done by other concrete specialists. In all there is first the concrete; second, vertical bars of metal, iron, or steel; third, bindings of sheet-metal or wire.

THE METHOD OF CONSTRUCTION

is very simple. A wooden box or mould is made in which the rods are set upright; one of the bindings is then put in, and about 6 in. or 12 in. of concrete well rammed down; another of the bindings is put in, and the process repeated. The special functions of the vertical rods are (*a*) to aid the concrete in resisting the compression due to the load; (*b*) to resist any tensile stress which may be set up in the concrete by unequal loading or by any want of homogeneity in the material itself, which tensile stresses cannot be safely left to the concrete to overcome. Almost all the makers of reinforced concrete constructions put their trust in the vertical rods of metal, as the special element adding strength to the concrete, if we may judge by the large proportion of metal so used, and by the rules employed to fix the safe load, which rules take no account of the binding.

INITIAL INTERNAL STRESSES.

If there were no initial stresses in the combination the load would be carried by the two materials in the inverse proportion of their rigidities—that is to say, if the concrete were ten times as easily compressed as the iron or steel, the iron or steel would be carrying ten times as much per square inch as the concrete. But the question is not so simple. Concrete setting in air shrinks, while concrete setting in water expands. Columns for buildings always set in air, and consequently the concrete shrinks. As the concrete adheres rigidly to the metal, the concrete is put in tension and the metal in compression—into a state of internal initial stress—before the load comes on. So strong is this action that the concrete may be at the limit of its tensile strength, and the metal at its elastic limit. No formula has so far been devised which takes this initial stress into proper account. The function of the bindings is to prevent lateral swelling and bursting. M. Considère's, was the first to give this its proper consideration and importance. In almost all columns, except M. Considère's, these bindings are usually about 6in. to 12in. apart, showing that the true use of the metal is not yet fully recognised. The author gave the results of some

EXPERIMENTS ON CONCRETE IN COMPRESSION,

armoured and unarmoured, referring to those carried out by Professor Gætana Lanza, and reported in the *Transactions* of the American Society of Civil Engineers" (1903, p. 487); by M. Gary, of the Ecole Polytechnique, at Charlottenburg; by the Commission des Voûtes de la Société des Ingénieurs et Architectes Autrichiens, reported on in 1901; and others by M. Considère described in his papers on "Resistance à la Compression du Béton Armé et du Béton Fretté," in *Le Genie Civil* (November and December, 1902). Reference was also made to the test of a column made by Messrs. Cubitt and Co., and tested at Messrs. Kirkaldy's Testing Works in June, 1904. As regards

FIRE-RESISTING PROPERTIES,

from all the reports on the Baltimore fire, where as intense heat was experienced as will ever occur, the armoured concrete constructions appear to have stood best. Concrete and iron or steel expand at about the same rate under changes in temperature, and the permanence of the concrete covering in fires is no doubt due to this. There is now no doubt that iron or steel buried in ordinary concrete remains uninjured by rust for generations. When an architect decides upon adopting reinforced concrete for a structure, or part of it, he will probably put the work in the hands of a concrete specialist, who makes his own calculations for the strength of the members, and arranges the details of the construction according to his own ideas. But as the responsibility must always in some measure lie with the architect, he will naturally want to check the specialist's work, particularly when the contract has been let in competition, and there is an object in the specialist endeavouring to reduce cost to a minimum.

Mr. L. G. Mouchel followed with a paper, illustrated with lantern slides, entitled

"MONOLITHIC CONSTRUCTIONS IN HENNEBIQUE FERRO-CONCRETE."

It had, he said, been his fate to be the pioneer of the new material in Great Britain. Having explained in detail the general principles of Hennebique ferro-concrete construction, Mr. Mouchel said that it was to its great simplicity, to the common-sense which had presided at its conception, that it owed its startling success. Any labourer of ordinary intelligence could be made an apt workman in the material in a few days. He himself had had to form his own gangs of men when he introduced ferro-concrete into this country, and it took him very little time to drill them in the practice of arranging the various parts of a work in which robustness was combined with simplicity. Respecting the theory of the system of construction, it was evident that the laws, formulæ, and methods of calculation used for ordinary materials could not be applied in structures composed of such heterogeneous substances as concrete and steel. It had been objected that their formulæ for ferro-concrete was empirical. It was not so, because they had not started their work on formulæ. It was only after many years' patient observation of the results obtained that they deduced the formulæ which were the bases of all their work in this absolutely novel material. Ferro-concrete was

AN ABSOLUTELY NEW MATERIAL,

which has come in its time to enrich the engineering world. It could not be treated as a combination of steel and concrete in which the properties of the component elements could be considered and treated separately. It had its own laws of detormation. Experiment demonstrated that a rectangular bar of concrete, when subjected to tension, showed an elongation at rupture, of, say, 1/10 inch; a bar of ferro-concrete, of the same external dimensions and made of the same concrete, showed at rupture an elongation of 1 inch; that is to say, ten times greater, before showing any crack or trace of disintegration, than in the first case. The elasticity of the new material was well known; it varied in notable proportions with the distribution of the steel in the mass of concrete. The so-called Hennebique's empirical methods could be relied upon with absolute confidence; for they had been the basis upon which over 12,000 different works had been constructed, and which, in almost every case, had been subjected to severe tests, the results of which had been carefully recorded.

TESTS.

As regards tests, the age of a piece of concrete is a most important element. Good concrete goes on increasing in quality year after year. It is not advisable to test to destruction samples a few weeks or a few months old. No two results will ever be alike, even on two samples of the same age, unless they are composed exactly of the same materials, mixed in identical proportions and by the same operator. The adherence of concrete to steel increases with the age of the work. Unlike construction in ordinary materials, which, if left to itself, will deteriorate, ferro-concrete construction goes on improving endlessly in quality with age. Tests must be made on the structures themselves. The Hennebique practice is always to test their structures within a very few weeks after completion with loads 50 per cent. in excess of the calculated load. When the load is removed, it is found that the floor, owing to the elastricity of ferro-concrete, regains its former level, or, at any rate, that the deflection, if any, will be quite inappreciable. It could not be otherwise, for any stress applied to any part of a well-made ferro-concrete floor affects not merely the part under the load, but also a very large area of the floor surrounding the part under observation. This is due to the absolute monolithism of the work. Besides static tests, there should be severe dynamic tests; without these the trials of a structure in which concrete and steel are combined are incomplete. The great security offered by ferro-concrete construction arises from the fact that it never collapses suddenly, but always gives, long beforehand, unmistakable warnings. The author described a test on a Hennebique beam which he had had carried out at Bermondsey. The beam was placed on two common concrete supports. Thirty tons—i. e.,

five times the calculated load—was put by degrees on the beam, when the operations had to be stopped, the pillars being crushed and having taken a slanting position, which caused the beam to twist badly. The load was then discharged. The deflection was measured at that point, and the following morning it was found that the floor had sprung back by 1in. The beam was cracked, but loading might have been continued for some time before complete destruction had not the supports given way.

THE VALUE OF MONOLITHISM.

Buildings of Hennebique construction have been subjected to very unforseen tests. At Lens, in the north of France, coal silos had been constructed of ferro-concrete 40ft. high, to contain 1,200 tons of coal. The silos were supported on fourteen pillars. One day, when they were quite full to the brim, a train of coal trolleys came into contact with one of the legs and broke it. The corner of the silo structure was thrown suddenly in cantilever; but owing to the monolithism of the whole building, no injury resulted to the silos themselves, nor to the other three pillars of the silo so affected. They merely had to reconstruct the broken pillar. A carshed of Hennebique construction at Le Mans was divided in two spans of 21ft. by a central line of ferro-concrete pillars. One of the cars coming down a gradient got out of control, ran off the metals, and dashed into the central pillar at the entrance of the shed and broke it. The span instantly became 42ft. instead of 21ft.; but notwithstanding this, the beams supported by that pillar held perfectly, and did not show the least trace of strain—another proof of the safety due to the monolithism of the ferro-concrete construction. The construction of

FERRO-CONCRETE PILES

the author described as one of the finest, most startling, and most useful applications of ferro-concrete. Their cost is little more than that of a timber pile, and they can bear safely a weight so much in excess of timber piles that a very considerable economy can be affected on the total cost of a foundation. At the present moment a foundation was being constructed in which the use of ferro-concrete piles procured a saving of over £12,000, as compared with the original estimate for timber piles. Judicious distribution of steel in ferro-concrete is at the root of success, whether it is in a beam, in a pillar, or in a floor—but, above all, in a pile.

THE ABSENCE OF VIBRATION.

Owing to the absolute monolithism of Hennebique constructions, they are far less liable to vibrations than ordinary constructions. One of the things which strike one most when entering a factory constructed entirely of ferro-concrete, where heavy machinery is at work, is the absence of vibrations and of noise. It is an everyday practice to attach shafting direct to the Hennebique pillars, which consequently have to sustain powerful lateral pulls. Heavy machinery—such as disintegrators grinding heavy materials, dynamos, and dynamo-motors—is also fixed direct on the Hennebique floors; and, after years of that treatment, the quality of the concrete has been found not to have suffered in the least.

FREEDOM FROM RUST.

Indisputable proofs have been given that the very best material to protect steel is concrete itself. Oxide of iron cannot exist in contact with concrete; rusted iron bars imbedded in concrete will, in the course of a month or so, be as bright as new. Concrete used in ferro-concrete is markedly different from ordinary concrete, both in its composition, in its make, and in the way it is employed. It is composed of materials of small volume (¾in. maximum for the gravel or stone), and the materials used are very clean. The proportions of sand and stone are always adjusted so as to give a concrete quite full—it is used in small quantities at a time, and so vigorously rammed that no cavities or porosity are possible. As regards the

ADHERENCE OF CONCRETE TO STEEL,

its value is such that it justifies the practice of some ferro-concrete builders who only reckon on concrete to make the junction between the different metallic parts of a structure. Experiments have demonstrated its surprising resistance to high temperature and sudden cooling. After the most destructive fires, Hennebique constructions have been found as strong as ever. As regards

ORNAMENTATION,

there is no reason why ferro-concrete buildings should not be made as artistic as constructions in ordinary materials. There is none that lends itself better—and more economically, too—than ferro-concrete to any shape that one may wish to give to it. To show the ease with which the material lends itself to ornamentation, a photograph was exhibited of the main reception-room in the extension recently carried out at the French Embassy in London. Except the external walls, the whole of the building is in ferro-concrete.

PROHIBITIVE LONDON BUILDING REGULATIONS.

In his concluding observations, the author referred to the mischief of the building by-laws in force in London. London enjoyed the unique privilege of being the only city in the civilized world where ferro-concrete constructions are actually prohibited. Building regulations of nearly every other city in the United Kingdom did not, read strictly, permit of the use of ferro-concrete; but, after intelligent and impartial investigation by the various authorities, Hennebique construction had been allowed. Such buildings have been erected in London, but only on ground belonging to railway and dock companies. These facts have been brought to the attention of the London County Council when they had been applied to for permission to erect similar buildings on ground within their jurisdiction; but in vain. They always met with the same reply:—"The Act Stipulates a certain thickness for walls. If you give your walls that thickness you can build." But to give ferro-concrete walls that thickness would be financially an impossibility and, practically speaking, an absurdity, since the comparatively thin walls of ferro-concrete are many times stronger and safer than those stipulated in the Act. He trusted that when the new London Building Act was framed, ferro-concrete construction would no longer be excluded. Ferro-concrete construction is absolutely safe; it cannot lend itself to the malpractices of the jerry-builder. Trickery is impossible with it. Should the contractor try to cheat, try to escape the specification, detection will not occur months or years after, but at once.

On account of the lateness of the hour at which the second paper concluded, 10.20 p.m., the Chairman suggested that any discussion should be postponed till the next meeting of the Institute, on Monday, Dec. 5.

ONTARIO HAS MARBLE.

Marble quarries of good quality are numerous in Ontario, although only two of them are being worked, says Inspector Carter, of the Bureau of Mines. One of the two in operation is near Renfrew, and the other at Halley Station, a short distance east. There are a number of unworked quarries in the counties of Hastings and Frontenac, and also in Algoma. The reason that there is so little marble quarried in Ontario is that Tennessee marble has gained the market, but that there is no reason why this state of affairs should continue, is shown by the interior of the Ottawa Parliament Buildings which is all Renfrew stone.

CARDINAL GIBBONS ON THE RIGHTS OF LABOR.

His opinion is as follows:—"The right of a non-union laborer to make his own contract freely, and perform it without hindrance, is so essential to civil liberty that it must be defended by the whole power of this Government."

MR. JOSEPH CONNOLLY.

Mr. Connolly's death, on Dec. 13, closes what was, until the last two or three years, a very active architectural career in Ontario. Mr. Connolly was in his 65th year. He was born in Limerick, but passed most of his life in this country. He was a member of the Irish Royal Institute of Architects, and was one of the most accomplished of Canadian architects. He was trained in the office of Mr. McCarthy, of Dublin, who held a similar position among Irish architects to that occupied by Sir Gilbert Scott in England. After serving for a time as Mr. McCarthy's chief assistant, and subsequently making a tour upon the continent for the sake of study, Mr. Connolly began practice in Limerick. He did not, however, remain long there, but came to Canada, and soon acquired the special practice for the Roman Catholic church which was his life's work, and which enabled him to continue always (excepting upon one or two occasions) to design in the style in which he was trained and in which he worked with freedom and originality. Besides a great deal in the way of alterations, additions and improvements to Roman Catholic churches and institutions, including the additions to St. Michael's Cathedral, in Toronto, and its decorations, the following buildings were his work:—

In Toronto: The Chapel of St. Joseph's Convent.
The south wing and Chapel of the House of Providence.
St. Paul's Church (Italian Romanesque.)
The Sunnyside Orphanage.
Some Roman Catholic Schools.
St. Mary's Church (his last work.)

In Kingston: The new front and tower of the Cathedral and several churches.

In Hamilton: The remodeling of St. Mary's Cathedral.
St. Patrick's Church.
The James Street Baptist Church.

In London: St. Peter's Cathedral and many Roman Catholic churches in the diocese.

The Franciscan Church in Chatham.

The Jesuit Church in Guelph.

Churches in Prescott, Kemptville, Tweed, Kincora, Formosa, Sault Ste Marie, Caledon, Arthur and many others, including St. Michael's church in Belleville, the destruction of which the other day was the cause of so many lamentations in Belleville.

An American Forest Congress will be held at Washington on Jan. 2-6, 1905, under the auspices of the American Forestry Association. Its purpose will be to establish a broader understanding of the forest in its relation to the great industries depending on it; to advance the conservative use of forest resources for both the present and the future need of these industries; and to stimulate and unite all efforts to perpetuate the forest as a permanent resource of the nation. This purpose is one which deserves the hearty support of engineers and architects, for the increasing cost of timber indicates that the time is soon at hand when forestry will become one of the most imperatively needed callings in the country. Anything that can be done to spread an appreciation of its importance deserves hearty support. The secretary of the Congress is Mr. W. L. Hall, Atlantic Building, Washington.

MOVING AND ERECTING LARGE GRANITE COLUMNS.

Around the altar of the Cathedral of St. John the Divine in New York, there is to be a semicircular row of eight granite columns 6 ft. in diameter and 54 ft. in height. Each column is made in two pieces, the lower one being 36 ft. long and weighing 90 tons. The upper one is seated without doweling on its flat top, has a length of 18 ft. and weighs 40 tons. The columns were quarried and cut at the Bodwell Granite Co.'s Fox Island quarries at Vinalhaven, Me. At first it was intended to make them monolithic and no special difficulty was experienced in quarrying full-length slabs from a stratum of about the required thickness. These were hand-dressed approximately cylindrical and the first one was successfully turned in the lathe but broke while being polished. The break was attributed to torsion and for the second column power was applied at both ends of the lathe. Notwithstanding this arrangement, the column broke during the roughing. It was then suggested that the trouble lay with the excessive bending stresses due to the very long unsupported length and a center support was provided for the third column. This column broke more quickly than either of its predecessors and the attempt to make them monolithic was then abandoned.

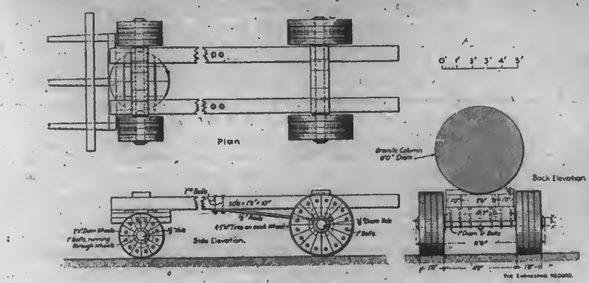
The shorter pieces were turned and polished without difficulty and were then enclosed in cylindrical cases made with 3 x 4 in. steel-hooped wooden staves set close together and secured to circular end pieces. They were loaded on barges, two complete columns to each, and were towed to New York. Skids were arranged from the deck to the shore and several turns of wire cable were taken around the middle of the column. One end was made fast to a hoisting engine and the free end was kept tight as the rope was overhauled and rolled the column easily to shore. Each piece was loaded on a special wagon and transported over a mile through the city streets and up a considerable grade to the site.

The wagon was built in Maine expressly for use on this work and is of simple and massive construction. It consists essentially of two pairs of wheels, two longitudinal beams and two cradles on the axles, and is built entirely of wood except the axles, tires and a few bolts and small braces. The 10 x 12-in. longitudinal timbers are 30 ft. long, are 3½ ft. apart on centers and overhang the front and rear axles about 2 ft. and 5 ft., respectively. The 8 x 8-in. rear axle and the 7 x 7-in. front axle each has six U-bolts fastening a solid 10 x 14-in wooden bolster to the upper side. On the front axle the bolster supports a horizontal wooden turntable platform or fifth wheel, on which the longitudinal timbers are seated. At the rear end they are seated directly on the bolster. Solid fillers are put on the axles between and above the longitudinals and are concaved on the upper surface to a radius of 3 ft. to receive the columns which are thus supported about 4 ft. clear of the pavement.

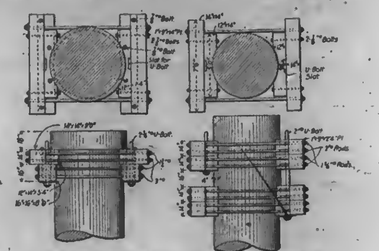
The rear wheels are about 4 ft. and the front wheels about 3 ft. in diameter, all of them being 20 in. thick and made with seven thicknesses of planed white oak plank. Each thickness is made of sixteen sectors in the large wheel and twelve sectors in the small wheel, bolted together and breaking joints in adjacent thicknesses. A steel disc is bolted to the center of the wheel on each side and through it and the solid planks a hole was bored to fit the axle, so that the bearing of the latter was on the ends of the fibers. The tires consist of four 5 x 1-in. welded rings sunk on each wheel. The rear wheels are provided with a break shoe operated by a screw, but it was seldom necessary use this, most purposes being served by a transverse timber chained to the axle and dragging on the ground close to the wheels, but clear of them so long as the wagon advances. If the wagon tends to move backwards, the timber immediately serves to chock the wheels.

The wagon was hauled by a six-part manilla rope tackle which had a clevis attachment to a sheave set in

the bight of a steel cable, one end of which was attached to the center of each axle, thus distributing the traction stress equally on both axles. The forward block in the tackle was attached to a 1½-in. wire rope anchored in front and the fall line was operated by the drum of a Lidgerwood hoisting engine. The hoisting engine was chained to a pair of bent hooks with their points turned vertically downwards in holes about 6 ft. apart which were made by the removal of single Belgian blocks from the pavements. The shanks of the hooks lay horizontal on the surface of the undisturbed pavement underneath a heavy transverse beam on which a traction engine was seated and furnished steam to operate the hoisting engine. This provided a very strong and simple anchorage which was shifted with ease and rapidity and involved no excavating or counterweights. The 1½-in. wire cable was made with several 50-ft. lengths each corresponding to the extended length of the tackle. When the tackle was pulled up so that the blocks nearly jammed, it was disengaged from the cable and a whip line attached to the forward block was reeved through a sheave hooked into the next joint of the cable and the free end was brought back to the capstan of the hoisting engine and wound up there so as to rapidly overhaul the tackle. The last length of the cable was disengaged, the tackle hooked on in its place and the cycle of operations repeated and so on, thus moving the column with very little loss of time. When the wagon was hauled up



Timber Truck for Columns.



Friction Clamps for Top of Column Sections.

close to the hoisting engine, the latter was pulled forward the full length of the cable by means of the traction engine and these operations were repeated until the columns arrived at the site.

The system worked satisfactorily and the wagon did not cause any injury to the pavement. The progress was absolutely steady and smooth on an up grade, but on a level or down grade it was noticed that the irregularities of the pavement caused slight deflections in he progress of the wagon, due to the twisting of the forward axle. The first column-section was drawn from the pier to the site in nineteen days. Some of the others were drawn in seven days each. The eight columns were transported in about six months with a force of four men and a superintendent.

At the site the column sections were revolved into vertical positions and hoisted by three tackles forming a thirty-part system suspended from a shear legs or breast derrick made with two Oregon pine timbers 98 ft. long hewed 2 ft. square for the lower 50 ft. and tapered thence to a diameter of 20 in. at the top, where they are capped with an oak timber. From this timber were suspended a pair of ten-part tackles and a single six-part tackle in the center, all of them reeved with ¾-in. steel rope. The center tackle was an independent one operated by a separate hoisting engine. The two side tackles were reeved with a single line common to both so as to equalize the stress between them and carry through single top and bottom sheaves so as to make up the thirty parts and lead each end to a separate Lidgerwood hoisting engine. By this arrangement equilibrium was maintained between all parts of the tackles and the stresses were equalized no matter whether the engines were working uniformly or simultaneously or not. It was considered that the eccentric stress in revolving the column from the horizontal to the vertical position would be dangerous for lewis bolts, and a special device was adopted for attaching the tackles to the upper ends of the columns during this part of the operation.

The 90-ton bottom sections of the columns were turned and polished up to a distance of 18 in. from the end, where a rough shoulder of a diameter of about 10 in. greater than the shaft was left to form a collar. On the under side of this collar a pair of concaved yoke pieces were bolted to and took bearing against it. Through each side was set a 2¾ in. U-bolt to which a sling was attached to receive the tackles. The lower end of the column was lifted and placed on rollers, tackles were attached to the upper end and operated to drag the column forward and lift it into a vertical position, when it was seated on the permanent base. The yokes were then removed and the enlarged upper end of the column was scabbed off by hand and the surface was dressed perfectly horizontal to a line marked by a diamond on the polished surface of the shaft.

The 40-ton upper sections of the columns were handled by a different method. No collar was left on the end of the shaft which was dressed to the exact dimensions. Two clamps made with pairs of solid oak yokes connected by two 1¾ in. and two 2-in. screw rods at each end were fitted to the top of the column about 16 in. apart and screwed up as tight as possible so as to develop a large amount of friction. A U-bolt of 2-in. iron was attached to one side of the upper yoke and a similar one was attached to the other side of the lower yoke, passing freely through a slot in the upper yoke. The hoisting sling was connected to these U-bolts and thus developed balanced eccentric stresses in both yokes, tending to cramp each one against the column and increase the friction, but maintaining equilibrium between themselves. This connection sufficed to revolve the column into a vertical position and it was temporily seated on the lower end, the yokes removed and a lewis bolt inserted in the top. The tackles were connected to the lewis bolt and lifted the column and seated it on the top of the lower section in its permanent position.

It required about one month to set up both sections of the column and prepare for the setting of the next column, but when everything was in readiness, the actual hoisting of the column occupied a very few minutes. Five of the columns have been erected and it is expected that two more will be erected this fall and the remaining one next spring. The total cost of the eight columns is about $155,000. Two years were required to quarry and cut them and about two years more will have been required to transport and set them. Messrs. Heins & La Farge are the architects of the cathedral and the columns have been made, transported and erected by Mr. John Peirce, contractor; Mr. Emil Diebitsch, chief engineer.

SANITARY REPORT ISSUED.

Dr. Louis Laberge, health officer for the City of Montreal, has just issued his thirty-first report, which contains some very interesting statitistics on the sanitary condition of Montreal city.

LEGAL.

A legal decision of both interest and importance to all concerned in the building trade and its allied professions was given last week by Mr. Justice Ridley, sitting without a jury. The question was apparently a simple one: If an architect and surveyor makes plans, drawings, specifications for an employer and is paid therefor, has the architect (in the absence of any special condition) the property in these documents? To that question some business men of experience would give a confident affirmative answer, while others would reply with a very emphatic negative. To state briefly the facts of this case (Gibbon *v* Pease), the plaintiff owned some property at Bayswater which he wished to convert into flats, and for that purpose he employed the defendant as his architect and surveyor, and an agreement was entered into by a firm of contractors, that they should execute the necessary work under the directions of the defendant. The local water company would not pass defendant's plans, whereupon Gibbon, the plaintiff, instructed a firm of plumbers to smooth over the difficulty, and to do that part of the work to the satisfaction of the water company. The defendant, not having any notice of this arrangement, expressed his annoyance that a professional slight had been put upon him. However, the work proceeded and was in due time finished, and upon its completion plaintiff asked his architect for his charges and paid them without demur. Gibbons thereafter asked Pease for the plans and other documents referring to the property, but Pease absolutely declined to hand them over, alleging that, beyond a *lien* for his charges, he had the absolute property in the documents according to a universal and well-known custom in the trade. Hence the action to compel defendant to hand them over. In the schedule of the Royal Institute of British Architects, paragraph 16 reads: "In respect of the ownership of drawings and specifications, it has hitherto been the general custom for the architect to be paid for their use only, *those documents remaining his property* . . . No authoritative decision in the courts of law has yet been given on the subject; it is therefore desirable, that for the present at least, that the architect should have a distinct understanding with his employer on this point."

Against this two strong opinions may be pitted. First, in his "Book on Buildings," Lord Grimthorpe sets out in full the standing form of agreement with an architect in use by the Commissioners of Works. There paragraph 6 runs: "The plans and the documents relating to the work shall be the property of the Commissioners—*i.e.*, at once; not merely after the work is done—and the architect shall make at his own expense all copies of them necessary for the conduct of the work." Secondly, paragraph 17 of the same is as follows: "No rules of the Royal Institute of British Architects or any other society to be held binding on the Commissioners."

It should be added that the decisions on the point under discussion are so uncertain and conflicting, that Mr. Justice Ridley felt himself compelled to take his own, and he entered judgment for the plaintiff, with stay of execution for three weeks pending an appeal. The matter will certainly go to the Court of Appeal, and we shall at last have a definite settlement of what has been for a long time a too-much-vexed question.—The (London) Contract Journal.

HOPEWELL v. KENNEDY.—Judgment by Chief Justice Meredith, in the Divisional Court, Toronto, on appeal by defendant from an order of the Judge of the County of Carleton, sitting at Ottawa Spring Assizes, for the Assize Judge. The action is for libel and being called for trial and before the empanelling of a jury, plaintiff's counsel moved for order to strike out certain paragraphs of defence and defendant's counterclaim. The order was made with leave to defendant to amend. The plaintiff, an Alderman of the city of Ottawa, and a member of the Building Committee of the Public Library, for the stonework and masonry of which defendant was contractor, made certain criticisms in committee in respect of work done by defendant upon the building. The libel complained of was embodied in a letter by defendant published in The Ottawa Evening Journal, 23rd October, 1903, in answer to plaintiff's criticisms. The point involved in the appeal is whether the defendant's statements were privileged. Held, that the plaintiff made no appeal to the public in offering his criticisms at a committee meeting, and that it was not open to defendant to enlarge the constituency created by the plaintiff and claim a privileged occasion. Some of the paragraphs are deemed admissible in mitigation of damages, and limited to that purpose, may be so pleaded. As to the counter-claim, held, that the reference therein to the charges as set forth in the statement of defence, and the further allegations that such charges were falsely and maliciously spoken by plaintiff, are quite sufficient to make the counter-claim in its present form a good pleading within rule 268. Appeal allowed as regards counterclaim and dismissed as regards statement of defence. Defendant may amend within five days. No costs of appeal on order appealed from. H. M. Mowat, K.C., for defendant. No one for plaintiff.

The new Union station at Toronto will cost $3,000,000 The architects who have been asked to prepare plans are Messrs. Darling & Pearson, Mr. E. J. Lennox, and Mr. A. H. Chapman.

Definite announcement is made of a new union depot for Emerson, Manitoba. Four of the five railroads entering the town vis., the Canadian Pacific, Great Northern, Canadian Northern, and Minneapolis, St. Paul & S. S. Marie Railway, will construct a new international union depot on the border where the four lines intersect. Owing to the fact that two of the companies interested are American and two Canadian a like portion of the depot will be placed on each side of the international line.

The Sackville Freestone Co., Limited

OWNS THE LARGEST AND BEST DEPOSIT OF

Red Freestone

OPERATED IN CANADA

The Stone is very easy to cut.

Stands a crushing test of 9130 lbs. to the inch and can be supplied in blocks of any size.

—THE—

CANADIAN ARCHITECT AND BUILDER

Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD)

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:
38 ALLIANCE BUILDING, MONTREAL.
Bell Telephone 2299.
720-721 UNION BANK BUILDING, WINNIPEG.
81 GREAT ST. HELENS, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements will be sent promptly on application. Orders for advertisements should reach the office of publication not later than the 18th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

THOS. CATTERALL - - - Treasurer

NOTES.

We regret to record the death of Mr. John Hillock, a well known figure among the builders of Toronto. Mr. Hillock, when making a Thanksgiving Day visit to his daughter, the wife of Dr. Addison, of Penetanguishene, caught a cold from which pneumonia developed. He was born in Toronto in 1834 and had lived there all his life. He is survived by four daughters, three of whom reside in Toronto.

Mr. John Moser, a well-known American architect, died at the age of seventy-two, at Atlanta. In early life he practised in Ohio and in Canada, but in his later years he settled in Alabama and Georgia, after having filled the place of a designer in the office of the Supervising Architect, under Mr. M. E. Bell. Amongst the buildings designed by Mr. Moser may be named the Cotton Exchange at Galveston, Tex., and St. Philip's Episcopal Cathedral in Atlanta, Ga., the latter being carried out in association with Mr. E. G. Lind.
